IMPORTANT NOTES:

1) This manual is valid for the following Firmware Versions:

   FIRMWARE VERSION   NOTE.

2) A Change Page may be included at the end of the manual. All applicable changes and revision number changes are documented with reference to the equipment serial numbers. Before using this Instruction Manual, check your equipment serial number to identify your model. If in doubt, contact your nearest Kepco Representative, or the Kepco Documentation Office in New York, (718) 461-7000, requesting the correct revision for your particular model and serial number.

3) The contents of this manual are protected by copyright. Reproduction of any part can be made only with the specific written permission of Kepco, Inc.

Data subject to change without notice.
Declaration of Conformity

Application of Council directives:
2006/95/EC (LVD)
2004/108/EC (EMC)

Standard to which Conformity is declared:
IEC61010-1, 3rd Edition
EN55011 (Class A, conducted & radiated)
EN61000-4-11, EN61000-4-4 Level 3, EN61000-4-2 Level 4, EN61000-4-5 Level 4. DESIGNED TO MEET: IEC61000-3-3, IEC61000-4-3, IEC61000-4-6, IEC61000-4-8.

Manufacturer's Name:
Manufacturer's Address:
KEPCO, INC.
131-38 SANFORD AVENUE
FLUSHING NY 11355
USA

Importer's Name:
Importer's Address:
Interface Card

Type of Equipment:
Model Series
Model No.

Year of Manufacture:

I, the undersigned, declare that the product specified above, when used in conjunction with the conditions of conformance set forth in the product instruction manual, complies with the requirements of the Low Voltage Directive 2006/95/EC, which forms the basis for application of the CE Mark to this product.

Place: Kepco, Inc.
131-38 Sanford Ave.
Flushing NY 11355

SECTION 1 - INTRODUCTION

1.1 SCOPE OF MANUAL

This manual contains instructions for the installation, operation and maintenance of the BIT 802E Interface Card manufactured by Kepco, Inc, Flushing, NY, U.S.A.

1.2 GENERAL DESCRIPTION

The Kepco BIT Card Series were designed as an accessory for the Kepco BOP series bipolar power supplies. The BIT 802E card makes it possible to control the BOP output by means of digital input signals via a LAN (Local Area Network) using SCPI commands. The BIT 802E card acts as an interface between the digital data bus and the BOP, accepting the digital input data and converting it to an analog signal, which in turn, controls the BOP output. The BIT 802E is fully compliant with the SCPI programming language.

At power-up the BIT 802E is set to local mode, allowing front panel control of the BOP power Supply. Upon power up the BIT 802E performs a reset, establishing the voltage and current output levels to be 0 volts and the output state to be off once a remote command is received.

The BIT 802E is a 16-bit interface card which allows either plus or minus voltage or current output at 15 bits of resolution.

Table 1-1 shows which specific revisions of BOP models are compatible with BIT 802E cards.

**TABLE 1-1. APPLICABILITY OF BIT 802E CARDS TO SPECIFIC BOP MODELS**

</table>

**NOTE:** For modification (to accept the BIT 802E card) of BOP Models with revision numbers that do not appear in this table, contact Kepco for assistance.

1.2.1 MEASUREMENTS

The readback information for BIT 802E cards is the average of the last 16 measurements. The measurement average is valid after a time delay which allows the readings to stabilize, plus 320 milliseconds.
1.2.2  LXI COMPATIBILITY

The BIT 802E is designed to meet the LXI Version 1.4 standard, providing the following stand-
dardized web interface capabilities for the user:

Discovery:
- MDNS (Bonjour - like the printer discovery)
- VXI-11 (National Instruments Ni Max, Agilent Io controller)

IP address support:
- DCHP
- AUTOIP
- Static IP (using Web Page)

Connections:
- SOCKET @ port 5025
- TELNET @ port 5024

Connection throughput:
- 25 milliseconds

1.3  SPECIFICATIONS

For voltage and current accuracy specifications of BOP Models with a BIT 802E card installed, refer to Tables 1-2 and 1-3, respectively. Table 1-4 lists the specifications for the BIT 802E card.

**TABLE 1-2. BOP VOLTAGE SPECIFICATIONS WITH BIT 802E INSTALLED**

SECTION 2 - INSTALLATION

2.1 UNPACKING AND INSPECTION

The Interface Card has been thoroughly inspected and tested prior to packing and is ready for operation following installation. Unpack, saving original packing material. If any indication of damage is found, file a claim immediately with the responsible transport service. See Table 2-1 for items supplied.

2.2 BIT 802E CARD, CONTROLS, INDICATORS, AND CONNECTORS

Figure 2-1 illustrates the location of controls, indicators and connectors of the BIT 802E Card.

- LAN Reset Switch - The LAN Reset switch is a pushbutton switch that requires a thin tool (e.g., the end of a paper clip) to activate. This switch restores the LAN interface configuration to the factory defaults presented in PAR. 4.2.
- LAN Indicator - During initialization the green LAN indicator blinks rapidly while attempting to locate a valid IP address. If successful, the LAN indicator stays on without blinking; when the LAN indicator is not lit it indicates failure to find a valid IP address. This indicator can be intentionally blinked using the ID INSTRUMENT feature of the web-based interface to identify which unit is being accessed in a multi-unit environment (see PAR. 4.3.3).
- Power On Indicator - The Power On LED is on as long as power is applied to the BOP.
- Ethernet (LAN) connector - Used to connect BOP/BIT 802E to a computer via the LAN interface. If the BOP/BIT 802E is connected through a switch hub or router, a standard ethernet cable should be used. However if connected directly to the computer's LAN port rather than through a switch hub or router, the connection must be made using a null modem (crossover) cable that reverses the transmit and receive pairs. NOTE: The BIT 802E LAN input does not do this swap automatically.

NOTE: The Rear Programming Connector shown in Figure 2-1 is fully described in the BOP documentation, and MUST be installed for the unit to operate.

2.3 INSTALLATION OF INTERFACE CARD INTO THE BOP

Refer to Figure 2-2 to install the BIT 802E interface card.

CAUTION: The BIT 802E card contains ESD sensitive components. Follow all procedures in effect at your facility for handling ESD sensitive components.

NOTE: Step numbers coincide with encircled numbers on Figure 2-2.

Step 1. Remove a-c power to BOP by disconnecting line cord.

Step 2. Remove BOP cover (see Detail A of Figure 2-2 for screw locations; for more detailed instructions see Section 5, Figure 5-1 of your BOP Instruction Manual).

Step 3. Locate rear bracket and note part number (on outside left edge):
   if P/N 128-1810 proceed to step 4.
   if not P/N 128-1810, stop installation. Unit does not meet minimum requirements; contact Kepco for assistance.

Step 4. Unpack the BIT 802E Card Installation components (PCB assembly, cables #1 and #2, three (3) hex nuts and bracket).

Step 5. Remove and discard rear cover plate (P/N 128-1811) and use associated hardware to install bracket supplied (P/N 128-2440).

Step 6. Remove J204 Connector Assembly (P/N 241-0680) from Location #1. Mount Connector J204 into Location #3 using hex nut (P/N 102-0084).

Step 7. Locate transformer T202 and unplug 3 pin connector from Location #4 only.

Step 8. Plug in 3-pin Connector from transformer, T202 (removed in step 7), into BIT 802E Card, Location #5.

Step 9. Install 5 pin connector of cable #2, P/N 241-1096, onto Location #6 of the BIT 802E card.

Step 10. Install BIT 802E Card into the guides, slide into position so that mounting holes in PCB Assembly line up with the two mounting posts on the BOP mounting bracket.

Step 11. Secure the BIT 802E Card to the Mounting Posts using two hex nuts (P/N 102-0084).

Step 12. Install Cable #1 (18-position connectors) to the BIT 802E Card, mate the other end of the cable with Location #1 on BOP A1 Assembly.

Step 13. Connect the loose end of the Cable #2 to Location #2 on BOP A1 Assembly.

Step 14. Mark “-802E” after Model No. on Nameplate (see Detail A).

Step 15. Reinstall BOP cover.

Step 16. Initialize the BIT card per PAR. 2.4, then proceed to step 17.

Step 17. Perform calibration procedure detailed in Section 3 of this manual.
FIGURE 2-2. INSTALLATION OF MODEL BIT 802E INTO BOP
2.4 INITIALIZATION OF THE BIT 802E CARD

When a BIT 802E Card is installed in a BOP it must be initialized prior to use. Initialization of the BOP/BIT 802E can be performed from the LAN port. The process can be accomplished using either the CVI driver (see PAR. 2.4.1) or by sending SCPI commands using a serial communication program (see PAR. 2.4.2).

2.4.1 INITIALIZATION USING CVI DRIVER

The initialization procedure uses the "soft" front panel which is part of the CVI driver for the BIT 802E. The CVI Driver can be downloaded from the Kepco website at: www.kepcopower.com/drivers.htm by choosing the appropriate model and CVI configuration.

1. Connect the BIT 802E Interface Card to a Microsoft Windows-based computer via the LAN connector (see Figure 2-1). Use either a standard ethernet cable if using a router or hub, or a crossover LAN cable if connecting the BIT 802E directly to a computer. The BIT 802E is not Auto-MDI-X enabled and requires the crossover cable for direct connection.

2. Apply power to BOP power supply - the BIT 802E Power On indicator goes on. The BIT 802E will beep for less than 1 second, then will be ready for use. The BIT 802E LAN indicator will blink while searching for a valid IP address, then stay on continuously when found. If the LAN indicator is off, a valid IP address was not found.

3. Refer to PAR. 4.3.2 to find the unit on the LAN. Once the unit is found, note the IP address.

4. Download the CVI driver from www.kepcopower.com/drivers.htm by choosing the appropriate BIT card model and CVI configuration.

5. Unzip the files and doubleclick on setup.exe to install the driver. The driver will install itself, plus a general VISA driver if a VISA driver is not already present on the host computer. The bit_mdac folder will be added to the Start - Programs folder. Doubleclick bit_mdac.exe to run the program.

6. At the Start-up screen (Figure 2-3), select LAN, then enter the IP Address noted in step 3 into the ADDRESS field and click CONNECT. Upon successful initialization the initialization window closes and the Power Supply Found field of the Start-up window (Figure 2-3) shows BIT 802E. Click Continue.

FIGURE 2-3. CVI DRIVER START-UP
7. Refer to Figure 2-4 and enter the following information:

NOTE: If window shown in Figure 2-4 does not appear, the BIT 802E card has already been initialized. If the BOP model does not match the unit found in step 3 above, contact Kepco Customer Support for instructions.

- **Select Model:** e.g., BOP 100-2.
- **Serial Number:** Enter serial number found on the rear nameplate of BOP power supply.
- **Option Number:** If unit is a special (modified) unit, enter 5-digit suffix found in the Manual Addendum
- **Click the Initialize Card button**

   NOTE: If initialization fails and an error message is displayed, repeat step 3, making sure that the proper information is entered

8. After initialization, proceed to PAR. 3.2 to calibrate the initialized unit, using the CVI driver as described in PAR. 3.2.2.

![FIGURE 2-4. BIT 802E CARD INITIALIZATION USING VISA DRIVER](image)

### 2.4.2 INITIALIZATION USING SCPI COMMANDS VIA TELNET

1. Connect the BIT 802E Interface Card to a Microsoft Windows-based computer via the LAN connector (see Figure 2-1). Use either a standard ethernet cable if using a router or hub, or a crossover LAN cable if connecting the BIT 802E directly to a computer. The BIT 802E is not Auto-MDI-X enabled and requires the crossover cable for direct connection.

2. Apply power to BOP power supply - the BIT 802E Power On indicator goes on. The BIT 802E will beep for less than 1 second, then will be ready for use. The BIT 802E LAN indica-
tor will blink while searching for a valid IP address, then stay on continuously when found. If the LAN indicator is off, a valid IP address was not found.

3. Refer to PAR. 4.3.2 to find the unit on the LAN. Once the unit is found, note the IP address.

4. Set up the LAN connection as indicated by the following steps.

   A. Go to the command prompt.

   B. Enter the following: \texttt{TELNET [ip address from step 3] 5024} and press [ENTER] (e.g. \texttt{TELNET 192.168.1.200 5024})

   C. Type \texttt{*idn?} and press [ENTER]

   D. Unit responds with the identifier string of the BOP, e.g.: \texttt{KEPCO, BOP 200-20}, with additional characters indicating the revision level of the firmware. If the model is not BOP 200-20, the BIT 802E card has already been initialized. If the BOP model does not match the unit found in step 3 above, contact Kepco Customer Support for instructions.

5. Send the password initialization string of: \texttt{SYST:PASS:CEN DEFAULT} and press [ENTER].

6. Send the BOP configuration code. The configuration code format is VOLTAGE,CURRENT; for example the 100 Volt, 1 Amp BOP 100-1M is identified as 100,1. The sequence to be sent is: \texttt{DIAG:PST 100,1 and press [ENTER]}

7. Calibrate the unit per PAR. 3.2. Failure to calibrate the unit will result in the \texttt{*TST?} query reporting a FLASH memory error.

8. After the calibration has been completed, the master calibration levels can be established by sending the following command: \texttt{CAL:COPY WORK FACT} and press [ENTER].

2.5 INITIAL CHECK-OUT PROCEDURE

After the BIT 802E card has been installed per PAR. 2.3, initialized per PAR. 2.4, perform the following procedure to verify that it is functioning properly.

1. Connect the unit to a computer as specified in steps 1 and 2 of PAR. 2.4.1 or 2.4.2.

2. Using a thin tool (e.g., the end of a paper clip), press then release the LAN Reset pushbutton switch on the BIT-802E (see Figure 2-1). The LAN indicator will blink briefly, then remain on.

3. Refer to PAR. 4.3.2 to find the unit on the LAN, then launch the web page to view the Instrument Home page (Figure 4-4). Verify the model is correct, matching the voltage and current of the BOP.

4. Click on the OPERATE INSTRUMENT tab of the home page. Leave password blank and click Submit to access the Operate Instrument page (see Figure 4-6).

5. From the Operate Instrument page, click the Output ON/OFF button at the upper right of the web page and verify the OFF indicator above the button changes to ON (green), indicating the output is on.

6. Set the unit to output 8.1V by entering 8.11 in the VOLTAGE field, then click SET. Verify the output of the BOP changes and the voltage indication is 8.1V on both the web page and the BOP front panel.
SECTION 3 - CALIBRATION

NOTE: The calibration procedures below are for the purpose of recalibration and for the case where the BIT card is installed by the user. Unless otherwise noted, syntax is in SCPI.

3.1 EQUIPMENT REQUIRED

The following is a listing of equipment required for calibration of the Interface Card installed in a Kepco “BOP” Series Power Supply:

A. Precision digital voltmeter (DVM), minimum resolution 7 digits (suggested):

B. Precision four-terminal current shunt (sense resistor) with suitable power rating and tolerance for the currents to be measured.

C. Heat sink, capable of dissipating 10 times power rating of sense resistor

D. Refer to Figure 3-1 for equipment connections.

NOTE: ALL SENSE RESISTORS MUST BE MOUNTED ON A HEATSINK WITH A MINIMUM SURFACE AREA OF 36 SQUARE INCHES TO MAINTAIN THERMAL STABILITY DURING CALIBRATION.

FIGURE 3-1. CURRENT SHUNT CONNECTIONS

3.2 CALIBRATION OF BIT 802E INTERFACE CARD

Calibration of the BIT 802E card is performed using SCPI commands. The Instrument driver available at www.kepcopower.com/drivers.htm provides a graphical interface with informational displays and prompts which lead you through the calibration of the BIT 802E card. This VISA compliant driver provides an interface to the BIT 802E socket. The Instrument Home page (see Figure 4-4) of the BIT 802E provides a valid VISA Resource String for using the driver.
Calibration using the graphical interface is described in PAR. 3.2.2; is an alternative to the graphical interface, the BIT 802E card can also be calibrated using the manual procedure described in PAR. 3.2.1.

NOTE: During calibration various circuits of the BIT 802E Interface Card are verified. If an error occurs during the verification process, the interface card will beep and an error 240, Hardware, will be placed in the error queue.

The calibration values for different BOP Models are defined in Tables 3-1 and 3-2 for voltage and current, respectively. For each step requiring a measurement during calibration the tolerance of the measurements are included in Tables 3-1 and 3-2 and are not repeated in the individual steps.

Table 3-3 lists suggested sense resistors and includes Kepco and Manufacturer's part numbers. The accuracy of these resistors is 0.1% and will result in a system accuracy of 0.11% if the listed values in Tables 3-1 and 3-2 are used. For a system accuracy of 0.01%, measure the actual value of the sense resistor accurate to 7 places. Then calculate the expected values per Table 3-2 notes A-E; use with the listed tolerances of Table 3-2 to perform the calibration.

NOTE: ALL SENSE RESISTORS MUST BE MOUNTED ON A HEATSINK WITH A MINIMUM SURFACE AREA OF 36 SQUARE INCHES TO MAINTAIN THERMAL STABILITY DURING CALIBRATION (KEPCO P/N 136-0451 RECOMMENDED FOR KT SENSE RESISTORS LISTED).
3.2.1 MANUAL CALIBRATION

NOTE: The TCPIP socket interface of the BIT 802E is used to manually calibrate the BOP/BIT 802E. Many programs such as Hyperterminal or Procomm can be used, and an open source version that operates on Linux, Windows and a Mac is available at www.realtermsourceforge.net

1. Initiate calibration by sending the SCPI command `SYSTem:PASSword:CENable DEFAULT` and then send `CAL:STATe 1`. The password (DEFAULT) has been set at the factory. If the password has been changed from DEFAULT, substitute the correct password for the unit in the `SYST:PASS:CEN` command. If the password has been forgotten, consult factory.

If voltage calibration is not needed, proceed to step 16 for current calibration.

2. Set the BOP to zero volts output under the 1/4 range by sending `CAL:LVOLT ZERO`. Connect a Digital Voltmeter (DVM) to the BOP output to measure the power supply output. Send the Command `CAL:DPOT 32` to increase the output voltage until the DVM no longer changes in response to the command. Then send the Command `CAL:DPOT -32` to the unit. Adjust A1R81 on BOP until the DVM reads the voltage specified in Table 3-1 for LOW RANGE ZERO.

3. Set the BOP output voltage to zero by sending `CAL:VOLT ZERO`. Send the command `CAL:DPOT 1` to increase the voltage or `CAL:DPOT -1` to decrease the voltage until the DVM reads the voltage specified in Table 3-1 for VOLT ZERO.

4. Set the BOP to maximum positive output voltage by sending `CAL:VOLT MAX`. Measure the voltage output using a DVM of at least 7 digits in accuracy.

5. Decrease the voltage output by sending `CAL:DPOT -1` commands until the voltmeter reads less than the rated output voltage specified in Table 3-1 for MAX OUTPUT. Then send `CAL:DPOT 1` and verify the voltage is slightly above the rated output voltage specified in Table 3-1 for MAX OUTPUT.

6. Referring to Table 3-1 (HIGH RANGE ACCURACY) for value and ± tolerance, send the command `CAL:DATA -10` to decrease the voltage until the voltage is less than the rated output. Send the command `CAL:DATA 1` to increase the voltage or the command `CAL:DATA -1` to decrease the voltage until the DVM reads the value specified in Table 3-1 for HIGH RANGE ACCURACY MAX.

7. Set the BOP to maximum negative output by sending `CAL:VOLT MIN`. Continue to measure the output of the supply using the DVM.

8. If the output is less negative than the value specified in Table 3-1 for HIGH RANGE ACCURACY MIN, send `CAL:DATA -100` and verify the output is now more negative. If the value is still not more negative, send `CAL:DPOT -1` to change the course adjustment and provide a more negative output.

Send the command `CAL:DATA 10` to increase the voltage. Continue to send `CAL:DATA 10` until the voltage is less negative than the value specified in Table 3-1 for HIGH RANGE ACCURACY MIN. Send `CAL:DATA -1` until the reading is within the limits specified in Table 3-1 for HIGH RANGE ACCURACY MIN.
9. Set the BOP to 1/4 scale (low) range positive output voltage by sending \texttt{CAL:LVOLT MAX}. Output voltage should be as specified in Table 3-1 for LOW RANGE NOMINAL. Measure the voltage output using a Digital Voltmeter of at least 7 digits in accuracy.

10. Decrease the voltage output by sending \texttt{CAL:DPOT -1} commands until the voltmeter reads less than the rated output. Then send \texttt{CAL:DPOT 1} and verify the voltage is slightly above value specified in Table 3-1 for LOW RANGE NOMINAL.

11. Send the command \texttt{CAL:DATA -10} to decrease the voltage until the voltage is less than value specified in Table 3-1 for LOW RANGE ACCURACY MAX. Send the command \texttt{CAL:DATA 1} to increase the voltage or the command \texttt{CAL:DATA -1} to decrease the voltage to obtain the value specified in Table 3-1 for LOW RANGE ACCURACY MAX.

12. Set the BOP to maximum negative 1/4 scale range output by sending \texttt{CAL:LVOLT MIN}. Continue to measure the output of the supply.

13. If the output is less negative than the value specified in Table 3-1 for LOW RANGE ACCURACY MIN, send \texttt{CAL:DATA -100} and verify the output is now more negative. If the value is not more negative, Send \texttt{CAL:DPOT -1} to change the course adjustment and provide a more negative output.

   Send the command \texttt{CAL:DATA 10} to increase the voltage. Continue to send \texttt{CAL:DATA 10} until the voltage is less negative than the value specified in Table 3-1 for LOW RANGE ACCURACY MIN. Send \texttt{CAL:DATA -1} until the reading is within the limits specified in Table 3-1 for LOW RANGE ACCURACY MIN.

14. Set the BOP to voltage limit by sending \texttt{CAL:VPR MAX}. Continue to measure the output of the BOP.

15. Send the command \texttt{CAL:DATA -10} to decrease the voltage until the output voltage measured is within, or close to, the tolerance specified in Table 3-1 for VOLTAGE LIMIT ADJUST. Send the command \texttt{CAL:DATA 1} to increase the voltage or \texttt{CAL:DATA -1} to decrease the voltage as necessary until the measured value is within the tolerance specified in Table 3-1 for VOLTAGE LIMIT ADJUST.

   **NOTE:** If Current calibration is not required, proceed to step 31.

16. Send \texttt{CAL:ZERO} to prepare for current calibration. After sending the command, the BOP output will be set to zero volts. Connect the Kelvin type sense resistor to the BOP output using a heat sink capable of dissipating 10 times rated power of sense resistor. Connect the DVM to the sensing terminals of the Kelvin type sense resistor as shown in Figure 3-1. Table 3-2 provides suggested sense resistor values for various BOP current outputs, as well as the formula for calculating expected measured values and tolerances for any sense resistor where the precise resistance is known. Table 3-3 lists possible sources for obtaining the suggested sense resistors.

17. Set the BOP to zero volts across the sense resistor (corresponding to zero current) under the low (1/4 Scale) current range by sending \texttt{CAL:LCURR ZERO}. Monitor the DVM connected to the sense resistor. Adjust A1R83 on BOP (see Figure 2-1) until the DVM reads the voltage specified in Table 3-2 for LOW CURRENT ZERO.

18. Set the BOP current to 0 Amps in current mode by sending \texttt{CAL:CURR ZERO}. Use the command \texttt{CAL:DPOT 1} to increase the current or \texttt{CAL:DPOT -1} to decrease the current until the DVM reads the voltage specified in Table 3-2 for MAIN CURRENT ZERO.
19. Set the BOP to maximum positive output current by sending `CAL:CURR MAX`. Measure the voltage across the sense resistor using a Digital Voltmeter of at least 7 digits in accuracy. Verify the DVM reads the voltage specified in Table 3-2 for MAIN CURRENT NOMINAL. The voltage shown on the DVM should be positive; if not, reverse the leads to the DVM.

20. Decrease the voltage across the sense resistor by sending `CAL:DPOT -1` commands until the voltmeter reads less than the value specified in Table 3-2 for MAIN CURRENT NOMINAL. Then send `CAL:DPOT 1` and verify the voltage is slightly above the specified voltage.

21. Send the command `CAL:DATA -10` to decrease the voltage across the sense resistor until the voltage is less than the value specified in Table 3-2 for HIGH CURRENT ACCURACY MAX. Send the command `CAL:DATA 1` to increase the voltage or `CAL:DATA -1` to decrease the voltage until the DVM reads the voltage specified in Table 3-2 for HIGH CURRENT ACCURACY MAX.

22. Set the BOP to maximum negative output by sending `CAL:CURR MIN`. Continue to measure the voltage across the sense resistor.

23. If the voltage across the sense resistor is less negative than the value specified in Table 3-2 for HIGH CURRENT ACCURACY MIN, send `CAL:DATA -100` and verify the output is now more negative. If the value is not more negative than the value found in Table 3-2 for HIGH CURRENT ACCURACY MIN, send `CAL:DPOT -1` to change the course adjustment and provide a more negative output.

Send the command `CAL:DATA 10` to increase the voltage across the sense resistor. Continue to send `CAL:DATA 10` until the voltage is less than the value specified in Table 3-2 for HIGH CURRENT ACCURACY MIN. Send `CAL:DATA -1` until the DVM reads the voltage specified in Table 3-2 for HIGH CURRENT ACCURACY MIN.

24. Set BOP to the maximum current at low range (1/4 Scale) by sending `CAL:LCURR MAX`. Verify the DVM reads the voltage specified in Table 3-2 for LOW CURRENT NOMINAL.

25. Decrease the voltage across the sense resistor by sending `CAL:DPOT -1` commands until the voltmeter reads less than the value specified in Table 3-2 for LOW CURRENT NOMINAL. Then send `CAL:DPOT 1` and verify the voltage is slightly above this value.

26. Send the command `CAL:DATA -10` to decrease the voltage across the sense resistor until the voltage is less than the value specified in Table 3-2 for LOW RANGE ACCURACY MAX. If necessary, send the command `CAL:DATA 1` to increase the voltage across the sense resistor or `CAL:DATA -1` to decrease the voltage across the sense resistor until the DVM reads the voltage specified in Table 3-2 for LOW RANGE ACCURACY MAX.

27. Set the BOP to maximum negative 1/4 scale range output current by sending `CAL:LCURR MIN`. Continue to measure the voltage across the sense resistor.

28. If the voltage across the sense resistor is less negative than the value specified in Table 3-2 for LOW RANGE ACCURACY MIN, send `CAL:DATA -100` and verify the output is now more negative. If the value is not more negative, Send `CAL:DPOT -1` to change the course adjustment and provide a more negative output.

Send the command `CAL:DATA 10` to increase the voltage across the sense resistor. Continue to send `CAL:DATA 10` until the voltage is less than the value specified in Table 3-2 for LOW RANGE ACCURACY MIN. Send `CAL:DATA -1` until the reading is within the limits specified in Table 3-2 for LOW RANGE ACCURACY MIN.
29. Set the BOP to current limit by sending `CAL:CPR MAX`. Continue to measure the output of the BOP.

30. Send the command `CAL:DATA -10` to decrease the voltage across the sense resistor until the output voltage measured is within, or close to, the tolerance specified in Table 3-2 for CURRENT LIMIT ADJUST. Send the command `CAL:DATA 1` to increase the voltage or `CAL:DATA -1` to decrease the voltage as necessary until the measured value is within the tolerance specified in Table 3-1 for CURRENT LIMIT ADJUST.

31. Save the calibration levels by sending `CAL:SAVE 2/21/2015`. The 9 characters at the end are optional and are the calibration date of the power supply. The date entered in this manner is reported in the `*idn?` query. This can be prove useful for checking calibration dates when periodic calibration is imposed by system or quality requirements.

3.2.2 CALIBRATION USING IVI DRIVER

Calibration of the BOP with BIT 802E installed (BOP-BIT) is performed using SCPI commands implemented through the Instrument driver. The driver provides a graphical interface with informational displays and prompts which lead you through the calibration of the Power Supply.

The Web Interface Home page for the BIT 802E (see Figure 4-4) provides the VISA address string that can be copied and pasted into the IVI-COM driver when requested.

3.2.2.1 SETUP

1. The following calibration procedure uses a calibration panel which is part of the IVI driver for the BIT 802E which can be downloaded from the Kepco website at: www.kepcopower.com/drivers.htm
   Unzip the files and double-click on setup.exe to install the driver.

2. After the program is installed, double-click on \Program Files\Kepcodd\KepcoControlPanel\KepcoControlPanel.exe to run the program. Two windows appear: the VISA Resource Descriptor Input panel (Figure 3-2) and the Main Control panel (with display blank) as shown in Figure 3-3.

3. Enter the VISA resource descriptor (VISA address string, see Figure 4-4) of the BOP-BIT into the VISA Resource Descriptor Input panel (Figure 3-2), then click OK.

   ![FIGURE 3-2. INPUT VISA RESOURCE DESCRIPTOR](image)

4. The program will attempt to connect to the BOP-BIT. If connection is successful, the Main Control Panel display now shows the Instrument Model and Driver Revision as shown in Figure 3-3. If an Initialization Error message appears, either the IVI Shared components or VISA-COM was not installed correctly. Return to step 1 and reinstall the driver.
3.2.2.2 MAIN CONTROL PANEL

The main control panel allows setting the voltage and current, enabling and disabling the output, selecting the current range, resetting the unit, and calibrating the unit.

1. To set the unit's voltage and current, enter the values into the \texttt{Vset} and \texttt{Iset} boxes, respectively, and click the \texttt{SET} button.

2. To enable or disable the output, click the \texttt{OUTPUT} button.

3. To reset the unit to power-up state (output OFF, voltage and current set to 0), click the \texttt{RESET} button.

4. Range High and Range Auto radio buttons allow range selection.

3.2.2.3 CALIBRATION CONTROLS

\textbf{CAUTION}: Before performing calibration, set BOP OUTPUT to OFF and connect short across BOP output, then set OUTPUT to ON and Voltage to 10V. \textit{It is necessary to wait 10 minutes before calibrating the unit to allow for thermal stabilization.} After 10 minutes, set OUTPUT to OFF and remove short from BOP output, then proceed with calibration.

All adjustments are done using the four arrow buttons that appear during Calibration (see Figure 3-4 and Table 3-4). The double arrow buttons \texttt{<<} and \texttt{>>} either increase (\texttt{>>}) or decrease (\texttt{<<}) the output by a maximum of 18 steps (each step is one LSB (Least Significant Bit), equivalent to 0.024\% of nominal value) at a time; the \texttt{>} and \texttt{<} buttons either increase (\texttt{>}) or decrease (\texttt{<}) the output one step at a time.
3.2.2.4 CALIBRATION PROCEDURE

1. Click on the **Calibrate** button on the main control panel (see Figure 3-3). This opens a calibration panel (see Figure 3-4 and Table 3-4) that allows calibration in either voltage or current mode.

2. After initializing, the password window appears (see Figure 3-5). The password (DEFAULT) has been set at the factory. If the password has been changed from DEFAULT, type the proper password in the text box and click **OK**. If the password has been forgotten, consult factory. If the password is correct, the calibration panel (Figure 3-4) is active and calibration can be accomplished by following the screen prompts.
3. For Voltage Calibration, click **YES** button (see Figure 3-6).

![Unit Calibration](image)

**FIGURE 3-6. VOLTAGE CALIBRATION**

4. The text window reads **Connect DVM to Output Sense, Remove Shunt**. Remove any connections between +OUT and –OUT. Connect DVM (high) to +OUT and DVM (low) to –OUT, then click **OK** button.

**NOTE:** Use external DVM for all measurements.

5. The text window reads **LVOLT ZERO Adjust R81**. Adjust A1R81 on BOP until the DVM reads the voltage specified in Table 3-1 for LOW RANGE ZERO, then click **OK** button.

6. The text window reads **VOLT ZERO**. Using the < and > buttons (see PAR. 3.2.2.3), adjust the output voltage until the DVM reads the voltage specified in Table 3-1 for VOLT ZERO, then click **OK** button.

7. The text window reads **VOLT MAX**. Using the coarse << and >> and fine < and > buttons, adjust the output voltage until DVM reading is as specified in Table 3-1 for HIGH RANGE ACCURACY then click **OK** button.

8. The text window reads **VOLT MIN**. Using the coarse << and >> and fine < and > buttons, adjust the output voltage until DVM reading is as specified in Table 3-1 for HIGH RANGE ACCURACY, then click **OK** button.

9. The text window reads **LVOLT MAX**. Using the coarse << and >> and fine < and > buttons, adjust the output voltage until DVM reads voltage specified in Table 3-1 for LOW RANGE ACCURACY, then click **OK** button.

10. The text window reads **LVOLT MIN**. Using the coarse << and >> and fine < and > buttons, adjust the output voltage until DVM reads voltage specified in Table 3-1 for LOW RANGE ACCURACY, then click **OK** button.

11. The text window reads **VPR MAX**. Using the coarse << and >> and fine < and > buttons, adjust the output voltage until DVM reads voltage specified in Table 3-1 for VOLTAGE PROTECT ADJUST, then click **OK** button.

12. The text window reads **VPR MIN – No adjustment, check only.** Click **OK** button to proceed to next step.

13. The text window reads **VOLT CAL DONE**. A separate window opens and reads **Cal Current? no=skip**. Click **YES** button to perform current calibration.

14. The text window reads **Connect shunt across output**. Connect precision shunt resistor (see PAR. 3.1) across +OUT and –OUT terminals. After connecting the shunt click **OK** button.
15. The text window reads With shunt connected across output, connect DVM across shunt. Connect DVM (high) to the shunt sensing terminal that correlates to +OUT and DVM (low) to the shunt sensing terminal that correlates to –OUT. Click OK button to proceed to next step.

16. The text window reads LCURR ZERO Adjust R83. Adjust A1R83 on BOP until the DVM reads less than the voltage specified in Table 3-2 for LOW CURRENT ZERO, then click OK button.

17. The text window reads CURR ZERO. Using the fine adjust < and > buttons, adjust output until DVM reads voltage specified in Table 3-2 for MAIN CURRENT ZERO, then click OK button.

18. The text window reads CURR MAX. Using the coarse << and >> and fine < and > buttons, adjust output current until DVM reads voltage specified in Table 3-2 for HIGH CURRENT ACCURACY, then click OK button.

19. The text window reads CURR MIN. Using the coarse << and >> and fine < and > buttons, adjust output current until DVM reads voltage specified in Table 3-2 for HIGH CURRENT ACCURACY, then click OK button.

20. The text window reads LCURR MAX. Using the coarse << and >> and fine < and > buttons, adjust output current until DVM reads voltage specified in Table 3-2 for LOW CURRENT ACCURACY, then click OK button.

21. The text window reads LCURR MIN. Using the coarse << and >> and fine < and > buttons, adjust output current until DVM reads voltage specified in Table 3-2 for LOW CURRENT ACCURACY, then click OK button.

22. The text window reads CPR MAX. Using the coarse << and >> and fine < and > buttons, adjust output current until DVM reads voltage specified in Table 3-2 for CURRENT PROTECT ADJUST, then click OK button.

23. The text window reads CPR MIN - No Adjustment, check only. Click OK button to proceed to next step.

24. The text window reads CAL Done, Disconnect Shunt. Click OK. Current calibration is complete and automatically saved. Disconnect the external shunt and DVM.
SECTION 4 - OPERATION

4.1 GENERAL

The Kepco BOP Power Supply, with an installed BIT 802E Interface Card, may be programmed via a web interface using either web pages from a browser or using SCPI (Standard Commands for Programmable Instruments) via Telnet. SCPI provides a common language used in an automatic test system.

CAUTION: DO NOT repeatedly toggle the circuit breaker/switch as this may cause unit to fault. Set Power ON/OFF circuit breaker/switch on front panel to ON. If actuator does not lock when released, wait a few seconds before trying again. The circuit breaker is "trip-free" design; if overload exists, contacts cannot be held closed by actuator.

NOTE: Upon power up, the BOP output is set to off, VOLTage and CURRent are set to 0. VOLTage and CURRent commands will not change the BOP output until the command OUTPut ON is sent to the BOP/BIT 802E.

4.2 LAN FACTORY DEFAULTS

The factory default LAN interface settings are listed below, however, actual unit settings may differ from those shown below depending upon whether the LAN is active (or connected).

- DHCP: ON
- AUTOIP: ON
- PING: ON (can only be changed through web interface)
- IP Address: Undefined
- MASK Address: 255.255.0.0
- GATE Address: 0.0.0.0
- DNS Address: 0.0.0.0

These default setting can be restored using the LAN Reset button (see Figure 2-1) or configured as desired from the web interface (see PAR. 4.3.4).

If the LAN connection is active when the LAN Reset button is pressed, the default values are as shown above, except that IP, MASK, GATE and DNS addresses are retrieved from the LAN or router and may differ from values shown

4.3 REMOTE PROGRAMMING USING THE WEB INTERFACE

Remote programming of the BOP/BIT 802E via the LAN port can be accomplished using a standard web browser connected to the internet. The factory default LAN settings of the BOP/BIT 802E are DHCP on, AUTOIP on. When source power is applied to the power supply (e.g., circuit breaker switched on), it first tries to find a DHCP server and get an IP address; during this time the BIT 802E LAN indicator continues to blink. If a server is found and an address assigned, the LAN indicator stays on without blinking.
If the server is not found after approximately 10 seconds, a duplicate address is supplied by the DHCP, however if DHCP has been disabled, the unit will use AUTOIP to get an address; if an IP address is found, the BIT 802E LAN indicator stays on without blinking. The range of valid AUTOIP addresses is 169.254.000.000 through 169.254.254.255 inclusive. Note that the Network Mask default for AUTOIP is 255.255.000.000. If an IP address is not found after two seconds, the LAN indicator stays off.

4.3.1 TROUBLESHOOTING LAN COMMUNICATION PROBLEMS.

If the LAN indicator stays off:

- First verify that the host end of the LAN connection is active (switch or hub is powered on). These devices typically include indicators that indicate port activity, so if the port to which the power supply is connected is inactive (dark), try connecting to a different port.

- Inspect the LAN cable connections at both ends, ensuring that the plugs are fully engaged with their respective receptacles. Try replacing the LAN cable with a cable known to be good.

- If the BOP/BIT 802E is connected directly to the computer's LAN port rather than through a switch hub or router, the connection must be made using a null modem (crossover) cable that reverses the transmit and receive pairs. NOTE: The BIT 802E LAN input will not do this swap automatically.

If the LAN indicator is on without blinking, but communication problems persist:

- The cause may be a fixed address on the PC that is incompatible with the AUTOIP range (169.254.xxx.xxx) of the BIT 802E. Refer to PAR. 4.3.2 to find the BOP/BIT 802E on the LAN, then refer to PAR. 4.3.3 and launch the web interface to correct the address.

- Refer to PAR 4.3.3 for browser types and versions supported and settings required.

- There can be latent delays in establishing communication between various devices on the LAN network hub, especially when the devices are powered on asynchronously. As a result, a steady LAN indication may begin blinking again when another device or the host computer itself is subsequently powered on. While this is a normal occurrence that typically resolves itself within a few seconds, LAN communication is interrupted during that time. Should this occur, first activate all devices connected to the hub and wait until the BIT 802E LAN indicator is on steadily for several seconds before attempting to communicate with the BOP/BIT 802E.

4.3.2 FINDING KEPCO POWER SUPPLIES ON THE LAN (DISCOVERY)

The BIT 802E is compliant with LXI Version 1.4 and allows for multiple ways to locate units on the LAN:

- LXI Discover Tool (download from www.lxistandard.org
- Safari browser with Bonjour installed
- Kepco PSFind Utility (download from www.kepcopower.com/drivers/drivers-dl3.htm#802e)
4.3.2.1 PSFIND DISCOVERY

The PSfind utility finds all operational Kepco power supplies connected to the LAN and then shows the MAC and IP addresses of the models found. To run the utility from your PC download the psfind.zip file to your computer. Extract psfind.exe from the zip file to a location of your choice, then doubleclick psfind.exe to run the application. A separate window opens as shown on Figure 4-1.

![FIGURE 4-1. PS FIND SCREEN](image)

Once the search is completed, all found units are displayed in the Select a Unit window (the MAC address appears in parentheses). If you do not see your device in the Select a Unit window or if the icon to the left of the selected instrument is red (not green), make sure it is turned on and connected to the network, then click the Search Again button.

4.3.2.2 BONJOUR-ENABLED DISCOVERY

Figure 4-2 shows the BOP 100-1 with BIT 802E found among other Bonjour (MDNS)-enabled devices. Most printers and all LXI Version 1.4-compliant devices support the industry standard discovery methods requiring no user action.

![FIGURE 4-2. DISCOVERY USING SAFARI BROWSER WITH BONJOUR INSTALLED](image)
4.3.2.3 LXI DISCOVERY

Figure 4-3 shows a Kepco BOP 100-1M power found on the LAN using the LXI Discovery Tool.

![LXI Discovery Tool](image)

**FIGURE 4-3. TYPICAL SCREEN USING LXI DISCOVERY TOOL**

4.3.3 LAUNCH WEB INTERFACE

After finding the unit and selecting the desired unit on the LAN (see PAR. 4.3.2), click the Launch Webpage button to open the BOP/BIT 802E Instrument HOME PAGE (UNIT DESCRIPTION) in your default browser (see Figure 4-4). You can also launch the web page in any browser by entering the IP address as the URL.

NOTE: If source power to the BOP/BIT 802E is removed or lost while a browser window is open, communication with the BOP/BIT 802E cannot be restored until the present browser window is closed and a new window is opened.

Upon initial display of the web page, it is good practice to click the browser Refresh/Reload button once to ensure that the power supply information displayed is up to date, and not prior information recalled from the browser cache.

Although most current browsers will work, Kepco recommends the following as fully supported: Safari, IE 8.0 and higher and Firefox 1.0 and higher. Popup blocking must be disabled and Javascript must be enabled for proper operation. If popup blocking is enabled, it may prevent viewing of the help screens.

The BOP/BIT 802E Instrument Home page identifies the unit which has been accessed, including Manufacturer, Instrument, Description, LXI Version (1.4), Serial Number, Calibration Date, Hostname, MAC Address, LXI Firmware Revision and TCP/IP Address. Click the HELP box at the left of the screen for detailed explanations of each. These parameters cannot be changed by the user. The hostname ends with .LOCAL if the MDNS has been completely resolved. This feature allows for easy discovery through the MDNS or Bonjour common naming system.
Clicking the ID INSTRUMENT box at the left of the screen, causes the physical LAN indicator on the BIT 802E card of the selected unit to blink (see Figure 2-1), allowing visual confirmation as to which unit is selected. This is especially important if more than one unit is found on the LAN.

### 4.3.4 LAN CONFIGURATION USING WEB INTERFACE

From the Web Interface Home Page (Figure 4-4) click on CONFIGURE LAN at the left to view the LAN Configuration page (Figure 4-5). The parameters that can be configured from this page are Host Name (DHCP), Description, IP Address, Subnet Mask address, Default Gateway Address, and DNS Server Address. Separate check-boxes allow enabling of DHCP, AUTOIP and PING. Descriptions of these terms can be viewed by clicking the HELP box at the left. If a data entry fault condition exists, an alert window indicates the type of fault. Click OK to close the window; the SUBMIT button is disabled until the fault is corrected.

There are three passwords shown on this page which control access to the web pages only (not to be confused with the unit password (see PAR. 4.5.3) which is needed for calibration. All three web passwords described below are case sensitive.

**NOTE:** In cases where multiple users are expected to have access to the units, it is recommended that password access be used to restrict control of the unit to one user (functioning as a bus controller), while allowing other users viewing access. Allowing multiple users to issue commands to a single unit can cause unpredictable results and may cause the unit to lock up.

- **The OPERATE INSTRUMENT password** restricts the ability to modify the OPERATE INSTRUMENT page settings. The settings can still be viewed while password protected.
- **The CONFIGURE INSTRUMENT password** restricts the ability to change some INSTRUMENT configuration parameters shown on the CONFIGURE INSTRUMENT page.
- **The CONFIGURE LAN password** restricts the ability to change the LAN configuration parameters shown on the CONFIGURE LAN page (Figure 4-5.)
The factory default is that passwords are not needed to access password-protected areas and none of the three passwords are established. To set a password for the first time, leave the CURRENT field blank, enter the new password in the NEW and REPEAT fields, then click SUBMIT. Subsequent changes require the current password to be entered in the CURRENT field. If a password is lost or forgotten, the factory default state (no password required) can be restored by pressing the LAN Reset button on the BIT 802E (see PAR. 2.2).

To change a parameter, enter the correct data and/or click the appropriate check-boxes, then click SUBMIT to save the change or NO CHANGE to clear and reload the page without saving. If the data is not entered within 20 seconds after the last keystroke, the data will revert to the previous value. If the LAN CONFIGURATION password was set, you will be prompted to enter the password before the changes are accepted.

When SUBMIT is clicked after new IP address information is entered, the front panel LAN indicator blinks rapidly while the unit validates the IP address. If the address is valid, the browser returns to the INSTRUMENT HOME page (Figure 4-4). If the address entered is already in use, the following note appears towards the top of the page:

NOTE: IP Address is in use.
Click CONFIGURE LAN and choose another IP to correct.

An IP address that is not already in use must be entered and submitted, otherwise the browser will lock, requiring the browser to be closed and reopened.

### 4.4 OPERATING THE UNIT USING WEB INTERFACE

To operate the unit, click the OPERATE INSTRUMENT box at the left. A simulated front panel (see Figure 4-6) at the top of the screen shows 1) output voltage and current, 2) VOLTAGE or CURRENT is displayed above the MODE button if the unit is in voltage or current mode, respectively (** is displayed if state is unknown, web page will update within 10 seconds), and 3)
whether the output is on or off. An ON/OFF button can be clicked to turn the output on or off. A MODE button allows the user to change the BOP/BIT 802E operating mode (voltage or current).

A small white dot below the voltage display flashes to indicate the web page is communicating with the unit. If a fault condition exists, an alert window indicates the type of fault, and operation via the web is disabled. When the fault is corrected, click OK to close the alert window and resume operation via the web.

**NOTE:** If the OPERATE INSTRUMENT password has been set (see PAR. 4.3.4), you will be prompted to enter the password before the OPERATE INSTRUMENT page settings can be changed.

The functions that the user can modify are listed on the black menu bar below the representation of the front panel: Output, Reset and List, and are described in the following paragraphs.

**NOTE:** Once data in a field has been changed, clicking the browser’s BACK button will cause all fields to revert to their previous values.

![Figure 4-6. WEB INTERFACE OPERATE INSTRUMENT PAGE](image)

### 4.4.1 Changing the Output

The Output dialog box opens when the OPERATE INSTRUMENT page is first opened, or when OUTPUT is clicked (see Figure 4-6). To set output voltage or current, enter the values and click SET. Voltage and current settings are not allowed to exceed the model setting. Attempts to set voltage or current beyond these limits will not be accepted. To turn the output on or off, click the ON/OFF button within the simulated front panel.

#### 4.4.1.0.1 Resetting the Unit (**RST**)

Click RESET to open the Reset dialog box, then click **RST** button to reset power supply to the power on default state: setpoints to zero Volts and minimum Amperes, and output set to OFF. **RST** also clears all LIST entries.
4.4.1.1 USING A LIST (USER-PROGRAMMED SEQUENCES)

Using the LIST feature, up to 1000 locations are available for programming the BOP/BIT 802E output. These locations enable the user to program the output using sequential steps which may be initiated by a single command. The repeatable user-determined sequences are stored in volatile memory and are retained until reprogrammed, the power supply is turned off, operating mode (voltage or current) is changed, a calibration is performed, or a `LIST:CLea`r command is received.

**Create the List.** Click LIST to open the List dialog box (Figure 4-8). Depending on the operating mode selected, either the voltage list or current list dialog box will be displayed. Click the MODE button to change the mode. Each location defines the values for one step: voltage and current, and a dwell time duration (between 0.1 and 5.0 seconds).

**NOTE:** Dwell times down to 0.01 second can be obtained using SCPI commands via Telnet to generate the list (see Appendix B).

Click Add to List button to add a step (the information displayed in the Voltage, Current and Dwell boxes) to the List steps shown to the right.

**Clearing the List.** Once a LIST has been started, the individual steps can not be changed; the only option is to delete the LIST by pressing the Clear List button to start over. In addition, performing any of the following operations will also clear the list: changing overcurrent or overvolt-
age PROTECTION settings, unit RESET (clicking *RST), changing LIMIT MODEL settings and exiting the OPERATE INSTRUMENT page.

**Create Voltage or Current Ramps.** In addition to adding single steps, the user may add to produce voltage or current ramps. Clicking the Voltage Ramp or Current Ramp button opens similar dialog boxes (see Figure 4-9). Enter the starting and ending ramp values, the number of intermediate steps (including start and end), the total time (0.1 to 5.0 seconds) to go from the start to the end of the ramp, and a constant current (for voltage ramp) or voltage (for current ramp) for each step of the ramp. Dwell times for each step will be calculated by the firmware (total time/number of steps), and must be greater than 0.0005 second. Clicking the Create Ramp button adds the steps to the list as the firmware calculates the intermediate voltage values and dwell times required to produce the desired ramp. Ramps with many total steps may take a few seconds to process; the percentage complete is indicated below the Create Ramp button.

![VOLTAGE RAMP and CURRENT RAMP DIALOG BOXES](image)

**Execute the List.** Steps may be added to a list using Add to List, Current Ramp or Voltage Ramp buttons, however the total number of steps can not exceed 1000. To execute the list, enter the number of times the list is to be executed in the Loops box (1 to 256; 0 is continuous looping), set the output on (click the On/Off button if necessary) and click the Execute List button. While the list is running, the title of the Execute List button changes to Stop Execution. After the completion of the specified number of LIST cycles, the output stabilizes at the conditions in the last LIST step.

**Stop the List.** If the Stop Execution button is clicked to stop the list, the output stays on with the voltage and current at the list values prior to the stop command, and the Stop Execution button reverts to Execute List. If the Execute List button is clicked again, the list restarts from the beginning. If the list is stopped by clicking the *RST button, the output turns off and Output setpoints are reset to 0V, minimum current.

### 4.5 OPERATING THE UNIT USING TELNET

To operate the unit using Telnet, first refer to PAR. 2.4.2 and perform steps 1, 2 and 3 to comment the unit to a computer and discover the unit on the LAN. Once the unit is found, note the IP address. Then go to the command prompt and enter the following:

`TELNET [ip address from the discovery process] 5024` and press [ENTER]

(e.g. TELNET 192.168.1.200 5024 [ENTER])

Once connected, the unit can be operated using the SCPI commands listed in Appendices A and B. See PAR. 4.7 for an overview of SCPI syntax and structure. The following paragraphs explain recommended practices to use when controlling a BOP/BIT 802E power supply using SCPI commands via Telnet.
4.5.1 PROGRAMMING TECHNIQUES TO OPTIMIZE POWER SUPPLY PERFORMANCE

Proper programming techniques can offer significant response time improvement and reduce undesirable transients at the power supply output. The key to performance optimization is to minimize mode changes (voltage mode/current limit to current mode/voltage limit or vice versa). Mode changes should be limited to changes in load conditions (to which the power supply will respond automatically), or by programming the limit parameter when required by the user application.

The proper way to program the power supply is to initially program the operating parameter to zero and the complementary limit parameter to the desired maximum value. Subsequent commands should change only the operating parameter. (The operating parameter is the parameter that controls the output, e.g., voltage controls the output in voltage mode, current in current mode.) The complementary limit parameter should be programmed only when there is a need to change it.

4.5.1.1 SETTING BOP VOLTAGE AND CURRENT LIMITS

There are no voltage or current protection settings that can be accessed through the GPIB interface. The limit controls on the BOP front panel (with the screw driver adjustment) can be used to limit output voltage or current. The limit control settings from the BOP front panel are fixed and are not computer-controllable. A common use of these controls is to set -V limit to 0 to prevent the BOP from supplying a negative output voltage.

The BIT 802E controls the BOP via two channels: the main channel, which is defined by the operating mode, and the limit channel. In voltage mode, the main channel handles output voltage and the limit channel handles current limit. In current mode the main channel handles output current and the limit channel handles voltage limit.

- If the BOP is operating in voltage mode, sending VOLT sxxxx controls the main channel, and thus the output voltage (where s = sign, + or – and xxxx = the absolute value of output voltage). Sending CURR sxxxx controls current limit (where s = sign, + or – and xxxx = the absolute value of current limit).

- If the BOP is operating in current mode, sending CURR sxxxx controls the main channel, and thus the output current (where s = sign, + or – and xxxx = the absolute value of output current). Sending VOLT sxxxx controls voltage limit (where s = sign, + or – and xxxx = the absolute value of voltage limit).

4.5.1.2 AUTOMATIC RANGE OPERATION.

The BIT 802E has low and high ranges which are changed automatically when the main channel set point is changed from a value less than the 1/4 of the units operating capability to a value that is higher than 1/4 of the operating capability. The automatic gain change is enabled at power up, or by either the *RST command or a mode change command (FUNC:MODE).

An automatic range change can result in undesirable transients when passing through the quarter scale point as result of BIT 802E card gain change, depending upon the load at the output of the BOP. For example, with a 50V BOP in voltage mode, the quarter scale gain change is at 12.5V. When the unit is programmed from 12.5V to 12.6V, the gain of the BOP changes and a spike may be seen at the BOP output. A transient may also occur when changing from −5V volts to +50V as −5 volts is in the region between −12.5V and +12.5V and +50V is beyond the quarter scale region. When the unit is programmed to remain in full scale, the gain change does not occur and this eliminates the transient.
4.5.1.3 USING THE BIT 802E TO PRODUCE A SOFTWARE-TIMED RAMP AT THE BOP OUTPUT

If the power supply is intended to operate in a test application that requires a set of specific output voltages in a specific order and the number of points is more than the 1000 points available in the BIT 802E LIST command, a computer-controlled ramp can be used.

The recommended way to run a voltage ramp is to set the current limit to maximum plus at least 2% (or unit limit for max absolute value of the load). While in voltage mode, current limit is the absolute value of the programmed current.

Before running the ramp it is recommended that the scale be set to full scale using VOLT:RANG 1 to avoid any transients as explained in PAR. 4.5.1.2.

When installed, the Labview interactive example available on our web site creates a KpDCpwr directory in Labview's user.lib. This sub-directory contains various programs such as KepcoDCPwr Software Timed Ramp.vi. This vi is a software-timed linear ramp that is an example of using both the range command and the limits in generating a ramp. There is also a KepcoDCPwr Software Timed Current Ramp.vi for the same functionality in current mode. The BIT 802E has a maximum ramp step rate of 50 milliseconds.

4.5.2 MAKING SURE THE PREVIOUS COMMAND IS COMPLETE

Some SCPI commands require a flash memory update and can take an indeterminate amount on time to complete. These commands are:

- *SAV
- MEM:PACK
- MEM:UPD
- CAL:COPY
- CAL:SAVE
- SYST:PASS:NEW
- SYST:SEC:IMM

When sending these commands via Telnet, these commands require a query to be added to the command string to verify the previous command is complete. When the command is complete, the unit updates the status byte and indicates MAV (Message Available, bit 4 - see Table A-3) is true. MAV indicates that there is a response to be received by the computer, so when it becomes set, the unit is ready for its next command after reading back the data from the query that was added to the command string.

The *ESR? query is ideal to check if the previous command is complete since it returns either a 1 or 0. It is important that it be sent as a part of the same string as the command that causes a flash update. As an example, sending CAL:SAVE 12/31/2005:*esr? or *esr?;CAL:SAVE 12/31/2005 are valid command strings. Sending the commands separately will not verify that the previous command is complete. Figure 4-10 is a program written in Visual C, a trademark of Microsoft corporation, incorporating these techniques. The Visual C project for this example is part of the Sample VISA programs for Visual Studio file that can be downloaded from Kepco's Website (see www.kepcopower.com/drivers/drivers-dl3.htm#bit802e).

Failure to provide an adequate delay can result in:

- Commands that are not processed,
- The following command may be received in error, causing an error in the transmission,
- Unit lock-up requiring power cycling of the unit. If working via the GPIB bus, sending Interface Clear and Device Clear followed by *RST will unlock the unit.
FIGURE 4-10. PROGRAMMING EXAMPLE TO VERIFY PREVIOUS COMMAND HAS COMPLETED
(SHEET 1 OF 3)
/*
 * Now we will open a VISA session to a device at Primary Address 6.
 * You can use any address for your instrument. In this example we are
 * using GPIB Primary Address 6.
 *
 * We must use the handle from viOpenDefaultRM and we must
 * also use a string that indicates which instrument to open. This
 * is called the instrument descriptor. The format for this string
 * can be found in the NI-VISA User Manual.
 * After opening a session to the device, we will get a handle to
 * the instrument which we will use in later VISA functions.
 * The two parameters in this function which are left blank are
 * reserved for future functionality. These two parameters are
 * given the value VI_NULL.
 *
 * This example will also work for serial or VXI instruments by changing
 * the instrument descriptor from GPIB0::2::INSTR to ASRL1::INSTR or
 * VXI0::2::INSTR depending on the necessary descriptor for your
 * instrument.
 */
status = viOpen (defaultRM, "GPIB0::6::INSTR", VI_NULL, VI_NULL, &instr);
if (status < VI_SUCCESS)
{
    printf("Cannot open a session to the device.
");
    goto Close;
}
/*
 * Set timeout value to 5000 milliseconds (5 seconds).
 */
status = viSetAttribute (instr, VI_ATTR_TMO_VALUE, 5000);
/*
 * At this point we now have a session open to the instrument at
 * Primary Address 6. We can use this session handle to write
 * an ASCII command to the instrument. We will use the viWrite function
 * to send the string "*IDN?", asking for the device's identification.
 */
strcpy(stringinput,"*IDN?");
status = viWrite (instr, (ViBuf)stringinput, (ViUInt32)strlen(stringinput), &writeCount);
if (status < VI_SUCCESS)
{
    printf("Error writing to the device\n");
    goto Close;
}
/*
 * Now we will attempt to read back a response from the device to
 * the identification query that was sent. We will use the viRead
 * function to acquire the data. We will try to read back 100 bytes.
 * After the data has been read the response is displayed.
 */
status = viRead (instr, buffer, 100, &retCount);
if (status < VI_SUCCESS)
{
    printf("Error reading a response from the device\n");
}
else
{
    printf("%*s\n",retCount,buffer);
}
//** Set Output Volt & Curr Values & enable output **/
strcpy(stringinput, "volt 5;:curr 1;:outp on");
status = viWrite(instr, (ViBuf)stringinput, (ViUInt32)strlen(stringinput), &writeCount);
if (status < VI_SUCCESS)
{
    printf("Error writing to the device\n");
goto Close;
}
printf("ready - hit a key to continue\n"); getchar();

//** send measure volt & curr cmds & get response **/
strcpy(stringinput, "meas:volt?;:meas:curr?\n");
status = viWrite(instr, (ViBuf)stringinput, (ViUInt32)strlen(stringinput), &writeCount);
if (status < VI_SUCCESS)
{
    printf("Error writing to the device\n");
goto Close;
}
status = viRead(instr, buffer, 100, &retCount);
if (strchr(buffer, 10))
    strchr(buffer, 10)[0] = 0; // terminate the buffer so we don't get trailing garbage
if (status < VI_SUCCESS)
{
    printf("Error reading a response from the device\n");
}
else
{
    printf("Volt;Curr : %*s\n", retCount, buffer);
}
printf("ready - hit a key to continue\n"); getchar();

//** send a reset **/
printf("resetting\n");
strcpy(stringinput, "*rst\n");
status = viWrite(instr, (ViBuf)stringinput, (ViUInt32)strlen(stringinput), &writeCount);
if (status < VI_SUCCESS)
{
    printf("Error writing to the device\n");
goto Close;
}
printf("ready - hit a key to continue\n");

/*
 * Now we will close the session to the instrument using
 * viClose. This operation frees all system resources.
 */
Close:
printf("Closing Sessions
Hit enter to continue.");
fflush(stdin);
getchar();
status = viClose(instr);
status = viClose(defaultRM);
return 0;
}
4.5.3 PASSWORD SETUP.

To change a password send:

\[ \text{SYST:PASS:CEN DEFAULT} \]

\[ \text{SYST:PASS:NEW DEFAULT new_password} \]

If the password is lost, please contact the factory.

4.6 BUILT IN TEST

The BIT 802E card is designed to perform periodic testing of itself, power up testing and commanded testing. The testing is reported to the operator both by errors placed in the SCPI error queue and by issuing audible beeps.

The CVI driver and demonstration soft panel can be downloaded from the Kepco website at: www.kepcopower.com/drivers.htm. The driver and demonstration panel provide an easy way to verify BOP/BIT 802E performance. A description of the driver is included as an Adobe Acrobat™ PDF file.

4.6.1 POWER-UP TEST

The power up testing of the BIT 802E is similar to the \(*\text{TST}\) command (PAR. A.16). Portions of the card are verified on power-up and errors are indicated by the beep codes listed in Table 4-1. The failed test is repeated indefinitely.

4.6.2 CONFIDENCE TEST

The SCPI command \(*\text{TST}\) is used to perform a confidence test of the interface. It verifies the microprocessor memory, the timer, optical buffer and reference of the BIT 802E card. It does not affect the output of the BOP. This command returns a 0 for pass and number from 1 through 1023 to indicate the cause of the error. The test executes each of the subtests even when any one fails. If any test fails a bit is set in the error code which is returned to the user. The error codes returned are listed in Table 4-1

**Table 4-1. BUILT-IN TEST ERROR CODES**
4.6.3 BOP TEST

The DIAG:TST? Command performs a test of the BOP instrument. The test includes the BIT 802E internal tests of the DAC (Digital to Analog Converter), Limit and Op Amp circuits. If successful it programs the BOP in voltage mode to the positive and negative limits of the device. It also verifies the Limit operation of the unit in current mode by setting the unit for the rated maximum current delivery and verifies that the voltage limit set at one volt operates correctly. It also tests the readback voltages in both high and low scales.

CAUTION: TO AVOID DAMAGE TO THE LOAD, DISCONNECT THE LOAD BEFORE ISSUING THIS COMMAND. (DURING THE SELF-TEST, THE BOP IS PROGRAMMED TO FULL SCALE POSITIVE AND FULL SCALE NEGATIVE OUTPUT.)

This command returns a 0 for pass, or a number from 1 through 1023 to indicate the cause of the error. The test executes each of the subtests even when any one fails. If any test fails, a bit is set in the error code which is returned to the user. The error codes returned are listed in Table 4-1.

4.7 SCPI PROGRAMMING

SCPI (Standard Commands for Programmable Instruments) is a programming language conforming to the protocols and standards established by IEEE 488.2 (reference document ANSI/IEEE Std 488.2, IEEE Standard Codes, Formats, Protocols, and Common Commands). SCPI commands are sent to the Interface Card as output strings within the selected programming language (PASCAL, BASIC, etc.) in accordance with the appropriate TCPIP function for port number 5025.

4.7.1 SCPI MESSAGES

There are two kinds of SCPI messages: program messages from controller to power supply, and response messages from the power supply to the controller. Program messages consist of one or more properly formatted commands/queries and instruct the power supply to perform an action; the controller may send a program message at any time. Response messages consist of formatted data; the data can contain information regarding operating parameters, power supply state, status, or error conditions.

4.7.2 COMMON COMMANDS/QUERIES

Common commands and queries are defined by the IEEE 488.2 standard to perform overall power supply functions (such as identification, status, or synchronization) unrelated to specific power supply operation (such as setting voltage/current). Common commands and queries are preceded by an asterisk (*) and are defined and explained in Appendix A. Refer also to syntax considerations (PARs. 4.7.2 through 4.7.5).

4.7.3 SCPI SUBSYSTEM COMMAND/QUERY STRUCTURE

Subsystem commands/queries are related to specific power supply functions (such as setting output voltage, current limit, etc.) Figure 4-11 is a tree diagram illustrating the structure of SCPI subsystem commands used in the Interface Card with the “root” at the left side, and specific commands forming the branches. The following paragraphs introduce the subsystems; subsystem commands that are defined and explained in Appendix B.
4.7.3.1 INITIATE SUBSYSTEM

This subsystem enables the trigger system. When a trigger is enabled, the triggering action will occur upon receipt of a GPIB <GET>, *TRG or TRIGger command. If a trigger circuit is not enabled, all trigger commands are ignored.

4.7.3.2 MEASURE SUBSYSTEM

This query subsystem returns the voltage and current measured at the power supply's output terminals.

4.7.3.3 [SOURCE:]VOLTAGE AND [SOURCE:]CURRENT SUBSYSTEMS

These subsystems program the output voltage and current of the power supply.

4.7.3.4 OUTPUT SUBSYSTEM

This subsystem enables/disables the power supply output. Voltage and current are determined by the combination of SOURCE subsystem VOLTage and CURRent commands and the load.

**FIGURE 4-11. TREE DIAGRAM OF SCPI COMMANDS USED WITH BIT 802E INTERFACE CARD**
4.7.3.5 LIST SUBSYSTEM

The LIST subsystem is used to generate transients, waveforms and execute a series of steps repeatedly. Up to 1002 power supply settings can be stored temporarily. Each setting consists of either a voltage or current value (depending on whether the power supply has been set to Voltage or Current mode), and a corresponding dwell time (the duration those settings are in effect). These settings may be executed in sequence as they are entered, or executed in a user-determined sequence that also allows individual settings to be repeated more than once. In addition, the entire sequence may be repeated for a specific number of times, or run indefinitely until commanded to stop. The sequence can also be run in reverse order to produce inverted waveforms. The following paragraphs provide guidance for using the list commands.

4.7.3.5.1 REQUIRED LIST COMMANDS

There are only five LIST commands, plus either the VOLT:MODE or CURR:MODE command, that are needed to create and execute a list. Use of these required commands is illustrated in Figure B-2 which shows the creation of sawtooth and triangular waveforms. LIST commands are not accepted while a list is running. Send VOLT:MODE FIX (PAR. B.59) or CURR:MODE FIX (PAR. B.50) to stop the list. A list remains in memory until the power is cycled or the LIST:CLEAR command is processed. Therefore, if the original list is unchanged, additional commands can be added to the end of the list without resending all the commands. However, to change parameters of one or more commands within the list, send LIST:CLEAR and then resend the entire list including the changed parameters. To execute the list again, either VOLT:MODE LIST or CURR:MODE LIST must be sent again.

LIST:VOLT (PAR. B.45) or LIST:CURR (PAR. B.31). These commands establish the points (steps) of a list which program output voltage or current. A list can only be either a voltage list or a current list, so the points in a list must be made with either LIST:VOLT XXXX or LIST:CURR XXXX. Mixing of these commands within a list is not allowed.

LIST:CLEAR (PAR. B.26). Always precede a new list with this command. A list remains in memory until the power is cycled or the LIST:CLEAR command is processed.

LIST:DWELL (PAR. B.36). Defines the dwell time for each point in a list. In many instances it is easier to use one dwell time and repeat a specific point multiple times to generate longer duration pulses. Remember, if more than one LIST:DWELL is sent, there must be a LIST:DWELL for each voltage or current point in the list.

LIST:COUNT (PAR. B.27) Defines how many times a list is executed. 0 equals indefinite; when a count of 0 is used, either *RST, VOLT:MODE FIX or CURR:MODE FIX must be used to stop the list. *RST will cause the output to be set off and the unit is set to Voltage mode. VOLT:MODE FIX or CURR:MODE FIX stops the list immediately; the point being executed when the list is stopped will be present at the BOP output.

4.7.3.5.2 OTHER REQUIRED COMMANDS

VOLT:MODE LIST (PAR. B.59) or CURR:MODE LIST (PAR. B.50). These commands start the list and VOLT:MODE FIX (PAR. B.59) or CURR:MODE FIX (PAR. B.50) stop the list. LIST commands are not accepted while a list is running. If LIST:COUNT is between 1 and 255, when the count decrements to 0, the list stops and the unit automatically moves to VOLT:MODE FIXED or CURR:MODE FIXED state. To execute the list again, either VOLT:MODE LIST or CURR:MODE LIST must be sent again.
4.7.3.5.3 OTHER USEFUL COMMANDS

LIST:COUNT:Skip (PAR. B.29). This command provides the ability to execute the initial points only once whenever a list is run. It is used to set initial preconditions prior to running a repetitive sequence.

LIST:DIR (PAR. B.34) This command changes the order of the list.

LIST:VOLT:POINTS? (PAR. B.47) or LIST:CURR:POINTS? (PAR. B.33) These queries return the number of points in a list and provide a simple way to insure that all points entered were properly processed and as intended.

4.7.3.5.4 OPTIONAL COMMANDS

Most commands have associated Queries (?). These are useful for troubleshooting/debugging lists but are not needed in most cases.

The LIST:SEQ command is provided for backward compatibility. It is not recommended to be used in any new designs as it may be eliminated at some point in the future.

4.7.3.6 STATUS SUBSYSTEM

This subsystem programs the power supply status register. The power supply has two groups of status registers: Operation and Questionable. Each group consists of three registers: Condition, Enable, and Event.

4.7.3.7 SYSTEM SUBSYSTEM

This subsystem is used to establish system settings Program Message Structure.

4.7.4 PROGRAM MESSAGE STRUCTURE

SCPI program messages (commands from controller to power supply) consist of one or more message units ending in a message terminator (required by Kepco power modules). The message terminator is not part of the syntax; it is defined by the way your programming language indicates the end of a line (such as a "newline" or "end-of-line" character). The message unit is a keyword consisting of a single command or query word followed by a message terminator (e.g., CURR?<NL> or TRIG<end-of-line>). The message unit may include a data parameter after the keyword separated by a space; the parameter is usually numeric (e.g., CURR 5<NL>), but may also be a string (e.g., OUTP ON<NL>). Figure 4-12 illustrates the message structure, showing how message units are combined. The following subparagraphs explain each component of the message structure.

NOTE: An alternative to using the message structure for multiple messages defined in the following paragraphs is to send each command as a separate line. In this case each command must use the full syntax shown in Appendix B.
4.7.4.1 KEYWORD

Keywords are instructions recognized by a decoder within the Interface Card, referred to as a "parser." Each keyword describes a command function; all keywords used by the Interface Card are listed in Figure 4-11.

Each keyword has a long form and a short form. For the long form the word is spelled out completely (e.g. STATUS, OUTPUT, VOLTAGE, and TRIGGER are long form keywords). For the short form only the first three or four letters of the long form are used (e.g., STAT, VOLT, OUTP, and TRIG).

To identify the short form and long form in this manual, keywords are written in upper case letters to represent the short form, followed by lower case letters indicating the long form (e.g., IMMEDIATE, EVENT, and OUTPUT). The parser, however, is not sensitive to case (e.g., outp, OutP, OUTPUT, ouTPut, or OUTp are all valid).

You must use the rules above when using keywords. Using an arbitrary short form such as ENABL for ENAB (ENABLE) or IMME for IMM (IMMEDIATE) will result in an error. Regardless of which form chosen, you must include all the letters required by that form.
4.7.4.2 KEYWORD SEPARATOR

If a command has two or more keywords, adjacent keywords must be separated by a colon (:) which acts as the keyword separator (e.g., CURR:LEV:TRIG). The colon can also act as a root specifier (paragraph 4.7.4.7).

4.7.4.3 QUERY INDICATOR

The question mark (?) following a keyword is a query indicator. This changes the command into a query. If there is more than one keyword in the command, the query indicator follows the last keyword. (e.g., VOLT? and MEAS:CURR?).

4.7.4.4 DATA

Some commands require data to accompany the keyword either in the form of a numeric value or character string. Data always follows the last keyword of a command or query (e.g., VOLT:LEV:TRIG 14 or SOUR:VOLT? MAX).

4.7.4.5 DATA SEPARATOR

Data must be separated from the last keyword by a space (e.g., VOLT:LEV:TRIG 14 or SOUR:VOLT? MAX).

4.7.4.6 MESSAGE UNIT SEPARATOR

When two or more message units are combined in a program message, they must be separated by a semicolon (;) (e.g., VOLT 15;MEAS:VOLT? and CURR 12;CURR:TRIG 12.5).

4.7.4.7 ROOT SPECIFIER

The root specifier is a colon (:) that precedes the first keyword of a program message. This places the parser at the root (top left, Figure 4-11) of the command tree. Note the difference between using the colon as a keyword separator and a root specifier in the following examples:

VOLT:LEV:IMM 16 The root specifier is not necessary for the first keyword and has been omitted. Both colons are keyword separators.

:CURR:LEV:IMM 4 Even though it is not required, it is still correct to include the root specifier (first colon). The other two are keyword separators.

VOLT:LEV 6;:CURR:LEV 15 The root specifier for VOLT is not necessary because it is the first keyword in the string and has not been included. The second colon is the root specifier for CURR and is required; if it is missing an error will result. The first and third colons are keyword separators.

:INIT ON;:TRIG;:MEAS:CURR?;VOLT? The first three colons are root specifiers. The fourth colon is a keyword separator.
4.7.4.8 MESSAGE TERMINATOR

The message terminator defines the end of a message. Three message terminators are permitted:

- new line (<NL>), ASCII 10 (decimal) or 0A (hex)
- carriage return (<CR>), ASCII 13 (decimal) or 0D (hex)
- both of the above (<CR> <NL>). If both are sent, the second is null and has no effect.

Your GPIB interface card software will automatically send a message terminator. For example, the HP BASIC OUTPUT statement inserts <NL> after the last data byte. When binary data is exchanged, <END> must be used. The combination <NL><END> terminator can be used for all data except binary data.

NOTE: Kepco power modules require a message terminator at the end of each program message. The examples shown in this manual assume a message terminator will be added at the end of each message. Where a message terminator is shown it is represented as <NL> regardless of the actual terminator character.

4.7.5 UNDERSTANDING THE COMMAND STRUCTURE

Understanding the command structure requires an understanding of the subsystem command tree illustrated in Figure 4-11. The "root" is located at the top left corner of the diagram. The parser goes to the root if:

- a message terminator is recognized by the parser
- a root specifier is recognized by the parser

Optional keywords are enclosed in brackets [ ] for identification; optional keywords can be omitted and the power supply will respond as if they were included in the message. The root level keyword [SOURce] is an optional keyword. Starting at the root, there are various branches or paths corresponding to the subsystems. The root keywords for the Interface Card are :INITiate, :MEASure, :OUTPut, [:SOURce], :STATus, and :SYSTem. Because the [SOURce] keyword is optional, the parser moves the path to the next level, so that VOLTage, CURRENT, and FUNCTION commands are at the root level.

Each time the parser encounters a keyword separator, the parser moves to the next indented level of the tree diagram. As an example, the STATus branch is a root level branch that has three sub-branches: OPERation, PRESet, and QUESTIONable. The following illustrates how SCPI code is interpreted by the parser:

STAT:PRES<NL>
The parser returns to the root due to the message terminator.

STAT:OPER?:PRES<NL>
The parser moves one level in from STAT. The next command is expected at the level defined by the colon in front of OPER?. Thus you can combine the following message units STAT:OPER? and STAT:PRES;

STAT:OPER:COND?:ENAB 16<NL>
After the OPER:COND? message unit, the parser moves in one level from OPER, allowing the abbreviated notation for STAT:OPER:ENAB.
4.7.6 PROGRAM MESSAGE SYNTAX SUMMARY

- Common commands begin with an asterisk (*).
- Queries end with a question mark (?).
- Program messages consist of a root keyword and, in some cases, one or more message units separated by a colon (;) followed by a message terminator. Several message units of a program message may be separated by a semicolon (;) without repeating the root keyword.
- If a program message has more than one message unit, then a colon (;) must precede the next keyword in order to set the parser back to the root (otherwise the next keyword will be taken as a subunit of the previous message unit).
  
  e.g., the command `meas:volt?;curr?` will read output voltage and output current since both `volt?` and `curr?` are interpreted as subunits of the `meas` command.

- Several commands may be sent as one message; a line feed terminates the message. Commands sent together are separated by a semicolon (;). The first command in a message starts at the root, therefore a colon (;) at the beginning is not mandatory.
  
  e.g., the command `meas:volt?;curr?` will read output voltage and output current, however the command `meas:volt?;:curr?` will read actual output voltage and *programmed current* since the colon preceding `curr?` indicates that `curr?` is not part of the `meas` command and starts at the root.

- UPPER case letters in mnemonics are mandatory (short form). Lower case letters may either be omitted, or must be specified completely (long form)
  
  e.g., `INSTrument` (long form) has the same effect as `INST` (short form).

- Commands/queries may be given in upper/lower case (long form)
  
  e.g., `SoUrCe` is allowed.

- Text shown between brackets [] is optional.
  
  e.g., `[SOUR::]VOLT[:LEV]:TRIG` has the same effect as `VOLT:TRIG`

4.7.7 SCPI PROGRAM EXAMPLE

Figure 4-13 is an example of a program written in Visual C using SCPI commands to program a BOP Power Supply. The Visual C project for this example is part of the Sample VISA programs for Visual Studio file that can be downloaded from Kepco’s Website (see www.kepcopower.com/drivers/drivers-d13.htm#bit802e). If it does not compile due to undefined functions, the issue is related to the importing of the visa.lib file in your project. This file is supplied and installed during the GPIB interface installation and may be located in a different place than our supplied project and must be corrected.

The program illustrated is for a configuration using a National Instruments GPIB interface card. (It will be necessary to consult the manufacturer’s data to achieve comparable functions with an interface card from a different manufacturer.) This program sets output voltage (Voltage mode) or voltage limit (Current mode) to 5V, and current limit (Voltage mode) or output current (Current mode) to 1A, then reads the measured (actual) voltage and current, then prints the measurements.

getchar();
4.8 ENHANCED OPERATION

The following paragraphs describe options that will permanently modify the behavior of the BIT 802E and associated BOP power supply. Although these options use SCPI commands, they are not intended to be used during normal programming of the BOP output.

The commands described in the following paragraphs affect only RAM variables. The power up state of the variables is retrieved from the FLASH EEPROM. The command MEMORY:UPDATE can be used to copy this RAM information to the FLASH EEPROM. The WINDOW variable is stored using the command MEM:UPDATE SHUTDOWN and the other variables, including the DIAG:SAV command, use the command MEMORY:UPDATE INTERFACE.

4.8.1 ERROR DETECTION

The BIT 802E card has the ability to alter the way the unit responds to detection of load and settings errors. The default behavior is for the BIT 802E to measure the main channel and verify that it is within the specified channel tolerances of the BOP, setting the appropriate bits in the Status Questionable register. This default behavior is established by the SYST:SEC:IMM command and the factory default window of 32 LSBs.

The default behavior can be modified using the DIAG:ERR, DIAG:ONL, DIAG:OFFL AND DIAG:WIN commands listed in Table 4-2 so that device errors are generated for conditions such as window exceeded, output current limit at setting and output current exceeding a hard limit. These errors can also be used to force the unit to go to an output off state upon detecting the errors. The behavior is altered, the new setting is stored in RAM and it remains in effect until a power off/power on cycle. The settings can be saved for power up by sending the MEMORY:UPDATE SHUTDOWN command. Error responses are listed in Table 4-2.
4.8.2 LIMIT CHANNEL CONTROL

The unit supports three limit settings for the output off state. The standard configuration is for the limits to be set to the minimum levels which causes the output not to vary beyond the BOX limits defined in the BOP manual. The limits can also be set to maximum or 110% of rated voltage or current. This is useful for battery operation. These limit settings are established by the DIAG:OUTPUT command. With other types of devices, it is possible to set the output off limit channels to be at any level by using the DIAG:OFFLimit commands to establish the limit for the output off state. DIAG:OUTP nH (see Table 4-2) controls the limit DAC values when the output is set to OFF; n = 0 is the default. This sets both voltage and current limit channels to 0 when the output is off. n = 1 sets voltage limit to maximum when the output is off. n = 2 sets the current limit to the maximum when the output is off. Bits 2 and 3 of the hex character allow the DIAG:OFFLimit commands to establish a specific voltage limit and current limit, respectively, when the output is off. Bits 0 and 2 or bits 1 and 3 should not be set at the same time since the maximum setting will override the value specified by DIAG:OFFLimit. The SYST:SEC:IMM command sets DIAG:OUTP n = 0. The variables are stored in non-volatile EEPROM by the command MEMORY:UPDATE INTERFACE.

4.8.3 USING AND SAVING SYSTEM VARIABLES

The DIAG:SAV command prepares the variables established by the SYST:SET command see (PAR. B.86) to be stored and used for subsequent power up cycles. However, executing SYST:SEC:IMM (PAR. B.85) restores the following configuration for subsequent power up cycles: LF0, DC0, RO0. In addition to initializing all the variables (except password) to the default state, SYST:SEC:IMM clears the SAV setup area and performs a PACK of the memory partitions (see PAR. 4.8.4).

Saving LF1 means that the unit will provide a line feed if the buffer is empty and a read is performed. Saving LF0 means that each string sent to the GPIB port causes a null string to be transmitted. The null string is a single Line feed character. This command is useful during program debug as a read without a query will not hold up the bus.

Saving DC0 means that DCL and SDC have no effect on the device (power supply) except to clear internal status registers. Saving DC1 means that DCL and SDC commands will function the same as the *RST command: the output is set to 0 Volts, 0 Amperes, voltage mode is selected and the output is set to OFF (unless RO1 is also set).

Saving RO0 causes the *RST command to set the output to 0 Volts and 0 Amps and sets output to OFF, requiring an OUTP ON command to be sent before voltage/current commands are present at the output. Saving RO1 causes *RST to set the output to ON and sets the output to 0 Volts and 0 Amps. Subsequent VOLT and CURR commands affect the output directly without having to send OUTP ON. The OUTP ON and OUTP OFF commands function normally to turn the output on and off.

4.8.4 FLASH MEMORY EEPROM OPERATION

The unit's configuration, voltage and current, saved setups (*SAV and *RCL command) and Calibration values are stored in Flash Memory. Since the Flash EEPROM cannot be modified by writing a single data byte, the block must be erased and then the data written into the correct locations.

The Bit 802E card accomplishes this by partitioning the Flash memory. As the amount of Flash memory used becomes larger with each subsequent data update, the Flash memory can fill up and needs to be compressed. The compression of the Flash EEPROM, called packing, is auto-
matically handled by the BIT 802E microprocessor's code. The packing process can take a half a second to accomplish. Because it is automatically executed, it can occur after any *SAV, Memory:UPDATE, or save of Calibration. When the memory is out of space, the internal microprocessor copies the live data to a backup flash area, erases the main flash data area, copies the current control variables into this clean space and then erases the backup flash area. The pack process can take 500 milliseconds to complete. Packing is automatically invoked during power up initialization if the BIT 802E card finds that any storage area is over 90% utilized.

The following statistics are a guide as to when a MEMORY PACK will occur.

- Save area - Approximately 300 *SAV operations can be completed before a PACK will occur automatically.

- Variable area - around 30 updates can be completed prior to an automatic PACK occurring. Variable areas also include serial number updates and password updates.

- Calibration - 16 calibrations can be saved before a PACK is required.

If the memory is over 80% full, the user can also initiate packing by sending the command MEMORY:PACK. Issuing a MEMORY:PACK command if the memory is less than 80% full will have no effect. Because this command may take a long time to complete, it is recommended that the user send MEMORY:PACK;*ESR?. The computer can then perform serial polls to wait for the command to complete. The command will be complete when the serial poll byte indicates there is data in the output buffer. (bit 4 set in the returned status byte).

| DIAG:OFFLimit:VOLT | DIAG:OFFLimit:VOLT? | The decimal value allows the user to establish the actual voltage limit DAC (digital to analog converter) setting when the output is off and the unit is in current mode. This variable is only used when bit 3 of the DIAG:OUTP register is set. The value is calculated using the equation:  
  \[
  \text{Voltage expected} / \left( \text{Voltage max} \times 1.1 \right) \times 256  
  \]
  The DVS standard setting is 0.  
  The query provides one byte which indicates the actual DAC current limit setting. |
| (xx = decimal value) |             | Factory default value: 0                                                                                                                                 |
| DIAG:ONLimit:CURR  | DIAG:ONLimit:CURR? | The decimal value allows the user to establish the actual current limit DAC (digital to analog converter) setting when the output is on and the unit is in voltage mode. This variable is only used when bit 7 of the DIAG:ERR:CURR register is set. The value is calculated using the equation:  
  \[
  \text{Current expected} / \left( \text{Current max} \times 1.1 \right) \times 256.  
  \]
  The DVS standard setting is 128 derived from \( \left( 1.1 / 2.2 \right) \times 256 \).  
  The query provides one byte which indicates the actual DAC current limit setting. |
| (xx = decimal value) |             | Factory default value: 0                                                                                                                                 |
| DIAG:ONLimit:VOLT  | DIAG:ONLimit:VOLT? | The decimal value allows the user to establish the actual voltage limit DAC (digital to analog converter) setting when the output is on and the unit is in current mode. This variable is only used when bit 7 of the DIAG:ERR:VOLT register is set. The value is calculated using the equation:  
  \[
  \text{Voltage expected} / \left( \text{Voltage max} \times 1.1 \right) \times 256  
  \]
  The DVS standard setting is 0.  
  The query provides one byte which indicates the actual DAC current limit setting. |
| (xx = decimal value) |             | Factory default value: 0                                                                                                                                 |
| DIAG:OUTP n        | DIAG:OUTP?  | DIAG:OUTP n controls the limit DAC values when the output is set to OFF. The values can either be set to maximum or to a user determined limit value (using the DIAG:OFFLimit commands. The SYST:SEC:IMM command sets \( \text{DIAG:OUTP n} = 0 \).  
  
  \[
  \text{DIAG:OUTP} 0 = \text{the default. This sets both voltage and current limit channels to 0 when the output is off. The four bits of the hex character are defined as follows:}  
  \]
  
  Bit 0 = 1 sets voltage limit to maximum when in Voltage mode and the output is off.  
  Bit 1 = 1 sets current limit to maximum when in Current mode and the output is off.  
  Bit 2 = 1 sets voltage limit to value determined by the DIAG:OFFLimit:VOLT command when the output is off.  
  Bit 3 = 1 sets current limit to value determined by the DIAG:OFFLimit:CURR command when the output is off.  
  
  For example, DIAG:OUTP 3 = sets both voltage and current limit to maximum. This can be useful for battery applications where the limit channel can allow the battery to discharge the battery voltage. Using both the maximum and DIAG:OFFLimit options (e.g., bits 0 and 2) at the same time is not recommended - the maximum value overrides the DIAG:OFFLimit setting. |
| (n = hex character) |             | (Returns hex character)                                                                                                                                 |
| DIAG:SAV           | n/a         | DIAG:SAV stores variables established by SYST:SET. (See PAR. 4.8.3 and B.82.)                                                                 |
|                    |             |                                                                                                                                              |

</tbody>
</table>

¹ The default window value of 32 indicates a 32 LSB margin for error during readback. The value for Readback is arrived at by taking 16 samples of voltage or current and averaging them. A readback error is produced when the calculated readback value (with calibration constants applied) exceeds the maximum readback (calculated readback + error window) or minimum readback (calculated readback – error window). Increasing the error window can avoid undesired errors. For example, in cases where the LIST command is used to produce a square wave output, overshoot inherent in the characteristics of the power supply can sometimes cause the readback average to increase enough to cause a readback error. Increasing the error window allows the square wave to be generated without producing an error.

| DIAG:RESTore TO FAC-TORY (double space required before and after TO) | None | Restores diagnostic settings to the default values and stores them in non-volatile memory. This is a password protected command. This command requires string TO FACTORY to execute correctly. Possible Errors:
-109,"Missing Parameter" - TO FACTORY was not found after command, double space is required on both sides of TO.
-203,"Command Protected" - syst:PASS:STAT? response not 1
-311,"Memory Error" - unable to store data, try again. |

---

4.8.4.1 CALIBRATION STORAGE

The BIT 802E maintains the calibration tables in Flash Memory until a PACK is executed. There are six calibration areas maintained in Flash Memory: Working, Prior, Oldest, Factory, Master, and First.

The calibration can be copied to another area using the CAL:COPY command. The syntax is as follows: CAL:COPY (source) (destination) where (source) and (destination) refer to the areas of Flash memory where calibration data is stored, designated as: WORKing, PRIor, OLDest, FACTory, MASTer, FIRst. Source refers to the calibration area that is to be copied, destination to the area that the calibration will be copied into.

The Master calibration should never be overwritten. Factory, Master, and First are set to the same values when a BIT 802E card is factory-installed in a BOP power supply. The Working calibration is the active calibration. Each time a CAL:SAV is executed, the values are saved in the Working (active) area. At the same time, the values previously stored in Working are moved to Prior, and the values previously stored in Prior are moved to Oldest. The values previously stored in Oldest are no longer available. Table 4-3 illustrates calibration storage and the use of the CAL:COPY command. An example is shown in PAR. 4.5.2

APPENDIX A - SCPI COMMON COMMAND/QUERY DEFINITIONS

A.1 INTRODUCTION

This appendix defines the SCPI common commands and queries used with the BIT 802E Interface Card. Common commands and queries are preceded by an asterisk (*) and are defined and explained in paragraphs A.2 through A.17, arranged in alphabetical order. Table A-1 provides a quick reference of all SCPI common commands and queries used in the Interface Card.

**A.2 *CLS — CLEAR STATUS COMMAND**

Syntax: *CLS

Description: Clears status data. Clears the error queue of the instrument. Forces power supply to "operation complete idle" and "operation complete query" state. Clears all Event Registers summarized in Status Byte Register without affecting the corresponding Enable Registers: Standard Event Status Register (ESR), Operation Status Event Register, Questionable Status Event Register, and Status Byte Register (STB). Related commands: *OPC. (See example, Figure A-1.)

**A.3 *ESE — STANDARD EVENT STATUS ENABLE COMMAND**

Syntax: *ESE <integer> where <integer> = positive whole number: 0 to 255 per Table A-2.

Default Value: 0

Description: This command programs the standard Event Status Enable register bits. The contents function as a mask to determine which events of the Event Status Register (ESR) are allowed to set the ESB (Event Summary Bit) of the Status Byte Register. Enables the Standard events to be summarized in the Status Byte register (1 = set = enable function, 0 = reset = disable function). All of the enabled events of the standard Event Status Enable register are logically ORed to cause ESB (bit 5) of the Status Byte Register to be set (1 = set = enable, 0 = reset = disable). (See example, Figure A-1.)

</tbody>
</table>
A.4 *ESE? — STANDARD EVENT STATUS ENABLE QUERY

Syntax: *ESE?
Return value: Integer> value per Table A-2.

Description: Returns the mask stored in the Standard Event Status Enable Register. Contents of Standard Event Status Enable register (*ESE) determine which bits of Standard Event Status register (*ESR) are enabled, allowing them to be summarized in the Status Byte register (*STB). All of the enabled events of the Standard Event Status Enable Register are logically ORed to cause ESB (bit 5) of the Status Byte Register to be set (1 = set = enable function, 0 = reset = disable function). (See example, Figure A-1.)

A.5 *ESR? — EVENT STATUS REGISTER QUERY

Syntax: *ESR?
Return value: <integer> (Value = contents of Event Status register as defined in Table A-2.)

Description: Causes the power supply to return the contents of the Standard Event Status register. After it has been read, the register is cleared. The Standard Event Status register bit configuration is defined in Table A-2 (1 = set, 0 = reset). The error bits listed in Table A-2 are also related to error codes produced during parsing of messages and to errors in the power supply (see PAR. B.76)

- Any 1xx type error sets the Command error bit (5).
- Any 2xx type error sets the Execution error bit (4).
- Any 3xx type error sets the Device error bit (3). The Device error bit will be set when Current Error or Voltage Error is detected and the corresponding Status Questionable bit is set (see PAR. B.28).
- Any 4xx type error sets the Query error bit (2).

Related Commands: *CLS, *ESE, *OPC. (See example, Figure A-1.)

A.6 *IDN? — IDENTIFICATION QUERY

Syntax: *IDN?
Return value: Character string

Description: Identifies the instrument. This query requests identification. The power supply returns a string which contains the manufacturer name, the model, the serial number and the firmware level. The character string contains the following fields: <Manufacturer>, <Model>, <Voltage>, <Current>, <Serial Number>, <Main revision>-<Flash revision> where: <Manufacturer> = KEPCO, <Model> = BIT 802E, <Serial Number> = SSSSSS <date> = (see CAL:SAVE DATE, PAR. B.11) <Main revision=n.m, e.g, 1.0) ><Firmware revision>=n.m (n.m revision, e.g, 1.0) (See example, Figure A-1.)
A.7 **OPC — OPERATION COMPLETE COMMAND**

**Syntax:**

```
*OPC
```

**Description:** Causes power supply to set status bit 0 (Operation Complete) when pending operations are complete. This command sets Standard Event Status Register bit 0 (see Table A-2) to “1” when all previous commands have been executed and changes in output level have been completed. This command does not prevent processing of subsequent commands, but bit 0 will not be set until all pending operations are completed. (1 = set = enable function, 0 = reset = disable function). (See example, Figure A-1.) As an example, the controller sends command(s), then sends *OPC. If controller then sends *ESR?, the power supply responds with either a “0” (if the power supply is busy executing the programmed commands), or a “1” (if the previously programmed commands are complete). (See example, Figure A-1.)

</tbody>
</table>

**FIGURE A-1.  GPIB COMMANDS**
A.8 *OPT? — OPTIONS QUERY
Syntax:  *OPT?
Returns string determined by power supply model.
Description: Causes the power supply to return an ASCII string which defines the functionality of the power supply. The functionality is defined as follows:

<table>
<thead>
<tr>
<th>STRING DATA</th>
<th>MEANING</th>
</tr>
</thead>
<tbody>
<tr>
<td>CAL</td>
<td>Support for CALibrate is present.</td>
</tr>
<tr>
<td>RL1</td>
<td>Commands sent over GPIB cause unit to enter remote mode (except for MEASure).</td>
</tr>
<tr>
<td>MEM</td>
<td>Indicates the number of memory steps supported.</td>
</tr>
<tr>
<td>LST</td>
<td>Indicates the number of LIST steps supported.</td>
</tr>
</tbody>
</table>

A.9 *RCL — RECALL COMMAND
Syntax:  *RCL <integer> (1 to 99)
Description: Restores power supply to previously defined levels of output voltage, output current and triggers. This command selects one of the 99 power supply memory locations, each of which stores values for output current, and output voltage and trigger levels. Executing a *RCL recalls the previously defined trigger settings from memory and places them in the trigger control section of the BIT 802E. Executing a second *RCL will cause the values in the trigger control section to be moved to the bit 802E output channel, allowing the power supply to operate with the recalled trigger information. The following parameters are affected by *RCL: VOLT:TRIG, CURR:TRIG, and FUNC:MODE:TRIG.

A.10 *RST — RESET COMMAND
Syntax:  *RST
Description: Resets power supply to the power on default state. The power supply output set to off (see DIAG:OUTP, Table 4-2, to establish the "off" state parameters) and the power supply is programmed to the power on values of the following parameters: CURR[:LEV][:IMM] = 0, VOLT[:LEV][:IMM] = 0, MODE = VOLT. If the power supply is in either an overvoltage or overcurrent state, this condition is reset by *RST. After sending *RST it is necessary to send OUTPUT ON for programmed values to appear at the output. The *RST command always returns the mode to Voltage and the range to automatic. (See example, Figure A-1.)

A.11 *SAV — SAVE COMMAND
Syntax:  *SAV <integer> (1 to 99)
Description: Saves the present state of output voltage, output current and trigger values, to the specified memory location. This command stores the present state of the power supply to one of 99 memory locations in Flash Memory (see PAR. 4.8.4). The following parameters are stored by *SAV: VOLT:TRIG, CURR:TRIG, and FUNC:MODE:TRIG. The stored values can be restored by the *RCL command.

A.12 *SRE — SERVICE REQUEST ENABLE COMMAND
Syntax:  *SRE<integer> where <integer> = value from 0 - 255 per Table A-3, except bit 6 cannot be programmed.
Description: Sets the condition of the Service Request Enable register. The Service Request Enable register determines which events of the Status Byte Register are summed into the MSS (Master Summary) and RQS (Request for Service) bits. RQS is the service request bit that is cleared by a serial poll, while MSS is not cleared when read. A "1" (1 = set = enable, 0 = reset = disable) in any Service Request Enable register bit position enables the corresponding Status Byte bit to set the RQS and MSS bits. All the enabled Service Request Enable register bits then are logically ORed to cause Bit 6 of the Status Byte Register (MSS/RQS) to be set. Related Commands: *SRE?, *STB?. (See example, Figure A-1.)
A.13 *SRE? — SERVICE REQUEST ENABLE QUERY
Syntax:  *SRE?  
Response:  <integer> = value from 0 - 255 per Table A-3.
Description:  Reads the Service Enable Register. Used to determine which events of the Status Byte Register are programmed to cause the power supply to generate a service request (1 = set = function enabled, 0 = reset = function disabled). Related Commands:  *SRE, *STB? (See example, Figure A-1.)

A.14 *STB? — STATUS BYTE REGISTER QUERY
Syntax:  *STB?  
Response:  <integer> value from 0 to 255 per Table A-3.
Description:  Reads Status Byte Register without clearing it. This Query reads the Status Byte Register (bit 6 = MSS) without clearing it (1 = set = function enabled, 0 = reset = function disabled). The register is cleared only when subsequent action clears all set bits. MSS is set when the power supply has one or more reasons for requesting service. (A serial poll also reads the Status Byte Register, except that bit 6 = RQS, not MSS; and RQS will be reset.) Related Commands:  *SRE, *SRE?. (See example, Figure A-1.)

A.15 *TRG — TRIGGER COMMAND
Syntax:  *TRG  
Description:  Triggers the power supply to be commanded to preprogrammed values of output current and voltage. When the trigger is armed (checked by examining WTG bit in Status Operational Condition register), *TRG generates a trigger signal. The trigger will change the output of the power supply to the output voltage and current levels specified by VOLT:TRIG and CURR:TRIG commands and clear the WTG bit in the Status Operation Condition register. If INIT:CONT has been issued, the trigger subsystem is immediately rearmed for subsequent triggers, and the WTG bit is again set to 1. *TRG or GET are both addressed commands (only devices selected as listeners will execute the command). Related Commands:  ABOR, INIT, TRIG, CURR:TRIG, VOLT:TRIG. (See example, Figure A-1.)

A.16 *TST? — SELF TEST QUERY
Syntax:  *TST?  
Returned value:  0 or non-zero (0 = pass test, non-zero = fail test)
Description:  Power Supply test. This query causes the power supply to do a self test and provide the controller with pass/fail results. A 0 is returned if the unit passes the test. If the unit fails, a number is returned to indicate the cause of the error. The test executes each of the subtests even when any one fails. If any test fails an error code bit is set which is returned to the user. The error codes returned are listed in Table 4-1.

A.17 *WAI — WAIT-TO-CONTINUE COMMAND
Syntax:  *WAI  
Response:
Description:  Causes the power supply to wait until all previously issued commands and queries are complete before executing subsequent commands or queries. This command can be used to guarantee sequential execution of commands and queries. When all pending operations are complete (all previous commands have been executed, changes in output level have been completed), the WAI command is completed and execution of subsequent commands can continue.
APPENDIX B - SCPI COMMAND/QUERY DEFINITIONS

B.1 INTRODUCTION

This appendix defines the SCPI subsystem commands and queries used with the BIT 802E Interface Card. Subsystem commands are defined in PAR. B.4 through B.88, arranged in groups as they appear in the tree diagram, Figure 4-11. Table B-1 provides a quick reference of all SCPI subsystem commands and queries used in the Interface Card.

### TABLE B-1. SCPI SUBSYSTEM COMMAND/QUERY INDEX

</table>

NOTE: Commands listed above that are followed by ", ?" have a related query.
B.2 NUMERICAL VALUES

The SCPI data parser on the BIT 802E supports a maximum of 8 digits after the decimal point and a maximum integer of \(4 \times 10^8\). Any values greater than these are not processed by the device and no error is generated. The largest string that can be received or transmitted by the BIT 802E is 253 characters.

All numerical data is returned in scientific notation, digits with decimal point and Exponent, e.g., \(2.71 \times 10^1\) for 27.1 after calibration constants have been applied. Thus, for example, \(\text{VOLT 14;VOLT?}\) may return \(1.39997 \times 10^1\) which indicates that the unit has been calibrated to provide 13.9997V for a programmed value of 14V, within the calculation accuracy of the BIT 802E. Error \(-120\) results from syntactical errors, e.g., the exponent exceeds 8, a letter is identified, etc. Error \(-222\) is produced if the value exceeds the range of acceptable values for the parameter.

B.3 CALibrate:CPRotect COMMAND

Syntax: Short Form: CAL:CPR {MIN | MAX}
Long Form: CALibrate:CPRotect {MIN | MAX}

Description: Selects Current Protection limit calibration, only effective with power supply in Calibrate status. CAL:CPR MAX selects maximum positive current protection limit calibration. CAL:CPR MIN selects maximum negative current protection limit calibration. Related Commands: CAL:STAT, CAL:ZERO, CAL:DATA, CAL:SAVE.

B.4 CALibrate:STATus COMMAND

Syntax: Short Form: CAL:STAT <boolean>
Long Form: CALibrate:STATus <boolean>
where boolean = 0 or OFF, 1 or ON

Description: Sets the power supply to Calibrate status. <boolean> 1 or ON causes power supply to enter Calibrate status. <boolean> 0 or OFF causes power supply to exit Calibrate status. If the wrong password was not enabled, error message -224 is posted to the queue. Related Commands: CAL:STAT, CAL:VOLT, CAL:CURR, CAL:ZERO, CAL:DATA, CAL:DPOT, CAL:SAVE. (See example, Figure B-1.)

B.5 CALibrate[:STATus]? QUERY

Syntax: Short Form: CAL:STAT? Long Form: CALibrate:STATus?
Return Value: <DATA>
where DATA = ZERO-ZERO, VOLT-ZERO, VOLT-MAX, VOLT-MIN, CURR-ZERO, CURR-MAX, CURR-MIN, or OFF.

Description: Identifies whether the power supply is in Calibrate status and indicates which calibration step is active. OFF indicates power supply is not in Calibrate status. ZERO-ZERO indicates power supply is at 0V, 0A, waiting for connection of load resistor. VOLT-ZERO indicates zero offset voltage adjustment is active. VOLT-MAX indicates maximum voltage adjustment is active. VOLT-MIN indicates minimum (negative) voltage adjustment is active. CURR-ZERO indicates zero offset current adjustment is active. CURR-MAX indicates maximum current adjustment is active. CURR-MIN indicates minimum (negative) current adjustment is active. Related Commands: CAL:STAT, CAL:VOLT, CAL:CURR, CAL:ZERO, CAL:DATA, CAL:DPOT, CAL:SAVE. (See example, Figure B-1.)
FIGURE B-1. USING CALIBRATION COMMANDS AND QUERIES

B.6 CALibrate:CURRent COMMAND

Syntax: Short Form: CAL:CURR {MIN | MAX | ZERO}  
          Long Form: CALibrate:CURR {MIN | MAX | ZERO}

Description: Selects Current calibration, only effective with power supply in Calibrate status.

CAL:CURR ZERO selects Current Zero Calibration. CAL:CURR MIN selects Current Full Scale Negative Calibration. CAL:CURR MAX selects Current Full Scale Positive Calibration. Normally Current Zero is done first, then Current Full Scale Positive Calibration. Related Commands: CAL:STAT, CAL:VOLT, CAL:LVOLT, CAL:LCURR, CAL:CURR, CAL:DATA, CAL:ZERO, CAL:SAVE. (See example, Figure B-1.)

B.7 CALibrate:DATA COMMAND

Syntax: Short Form: CAL:DATA {N}  
          Long Form: CALibrate:DATA {N}

Description: Provides fine adjustment of output during calibration only; Increases or decreases output by N LSB’s. CAL:CURR -N decreases output by N LSBs. CAL:CURR N increases output by N LSBs. This command is used during calibration to adjust the output for zero calibration as well as full scale calibration. This command is only effective if Calibration status is active. Related Commands: CAL:STAT, CAL:VOLT, CAL:VOLT, CAL:LVOLT, CAL:LCURR, CAL:CURR, CAL:DATA, CAL:DPOT, CAL:ZERO, CAL:SAVE. (See example, Figure B-1.)

B.8 CALibrate:DPOT COMMAND

Syntax: Short Form: CAL:DPOT {N}  
          Long Form: CALibrate:DPOT {N}

Description: Provides coarse adjustment of the output during calibration to within 5% of maximum and 2% of nominal; increases or decreases output by 50 LSB increments. Acceptable values of N are within ±32, corresponding to ±1600 (50 x 32) LSB’s. CAL:DPOT -N decreases output voltage by N LSBs. CAL:VOLT N increases output voltage by N LSBs. This command is used during calibration to adjust the output for Zero calibration as well as Full Scale Positive calibration. Output voltage is monitored on a calibrated digital multimeter and increased or decreased as required using this command. Output current is monitored on a calibrated digital multimeter (reading voltage at the sense terminals of the shunt resistor) and increased or decreased as required using this command. This command is only effective if Calibration status and either Voltage Zero, Voltage Maximum. Current Zero or Current Maximum calibration are active. CAL:STAT, CAL:VOLT, CAL:LVOLT, CAL:VOLT, CAL:CURR, CAL:DATA, CAL:ZERO, CAL:SAVE. (See example, Figure B-1.)
B.9 CALibrate:LCURR COMMAND

Syntax: Short Form: CAL:LCURR {MIN | MAX | ZERO}
Long Form: CALibrate:LCURR {MIN | MAX | ZERO}

Description: Selects low current range (1/4 scale) Current calibration, only effective with power supply in Calibrate status. CAL:LCURR ZERO selects Low Current Range Zero Calibration. CAL:LCURR MIN selects Low Current Range Full Scale Negative Calibration. CAL:LCURR MAX selects Low Current Range Full Scale Positive Calibration. Normally Low Current Range Zero is done first, then Low Current Range Full Scale Positive Calibration. Related Commands: CAL:STAT, CAL:VOLT, CAL:CURR, CAL:ZERO, CAL:DATA, CAL:DPOT, CAL:SAVE. (See example, Figure B-1.)

B.10 CALibrate:LVOLT COMMAND

Syntax: Short Form: CAL:LVOLT {MIN | MAX | ZERO}
Long Form: CALibrate:LVOLT {MIN | MAX | ZERO}

Description: Selects low voltage range (1/4 scale) Voltage calibration, only effective with power supply in Calibrate status. CAL:LVOLT ZERO selects Low Voltage Range Zero Calibration. CAL:LVOLT MIN selects Low Voltage Range Full Scale Negative Calibration. CAL:LVOLT MAX selects Low Voltage Range Full Scale Positive Calibration. Normally Low Voltage Range Zero is done first, then Low Voltage Range Full Scale Positive Calibration. Related Commands: CAL:STAT, CAL:VOLT, CAL:CURR, CAL:ZERO, CAL:DATA, CAL:DPOT, CAL:SAVE. (See example, Figure B-1.)

B.11 CALibrate:SAVE COMMAND

Syntax: Short Form: CAL:SAVE
Long Form: CALibrate:SAVE

Description: Saves computed calibration values in non-volatile memory. This command saves only the calibration values computed after entering Calibration status. If, for example, only Voltage calibration was performed, these are the only values saved. These values are stored in Flash Memory (see PAR. 4.8.4). Previous values are not lost, and can be restored (see PAR. 4.8.4.1). This command should be the last command before exiting Calibrate status. CAL:STAT, CAL:DATA, CAL:DPOT, CAL:VOLT, CAL:CURR, CAL:ZERO. (See example, Figure B-1.)

B.12 CALibrate:VOLTage COMMAND

Syntax: Short Form: CAL:VOLT {MIN | MAX | ZERO}
Long Form: CALibrate:VOLT {MIN | MAX | ZERO}

Description: Selects Voltage calibration, only effective with power supply in Calibrate status. CAL:VOLT ZERO selects Voltage Zero Calibration. CAL:VOLT MIN selects Voltage Full Scale Negative Calibration. CAL:VOLT MAX selects Voltage Full Scale Positive Calibration. Normally Voltage Zero is done first, then Voltage Full Scale Positive Calibration. Related Commands: CAL:STAT, CAL:VOLT, CAL:CURR, CAL:ZERO, CAL:DATA, CAL:DPOT, CAL:SAVE. (See example, Figure B-1.)

B.13 CALibrate:VPRotect COMMAND

Syntax: Short Form: CAL:VPR {MIN | MAX}
Long Form: CALibrate:VPRotect {MIN | MAX}

Description: Selects Voltage Protection limit calibration, only effective with power supply in Calibrate status. CAL:VPR MAX selects maximum positive voltage protection limit calibration. CAL:VPR MIN selects maximum negative voltage protection limit calibration. Related Commands: CAL:STAT, CAL:VOLT, CAL:CURR, CAL:ZERO, CAL:DATA, CAL:DPOT, CAL:SAVE.

B.14 CALibrate:ZERO COMMAND

Syntax: Short Form: CAL:ZERO
Long Form: CALibrate:ZERO

Description: Sets output to zero while calibration equipment connections are changed. This command is used when changing from Voltage to Current calibration or vice-versa. CAL:ZERO sets output voltage and current to zero. The user then connects or disconnects the shunt resistor or the digital voltmeter from the output terminals of the power supply as required for the subsequent Voltage or Current calibration. The next command should select the new parameter to be calibrated. Related Commands: CAL:STAT, CAL:VOLT, CAL:CURR, CAL:SAVE. (See example, Figure B-1.)
B.15 INITiate[:IMMediate] COMMAND
Syntax: Short Form: INIT[:IMM]  Long Form: INITiate[:IMMediate]
Description: Enables a single trigger. This command enables a single trigger. A *TRG command completes the sequence. Upon receipt of the *TRG command, the power supply will return to the commanded values of voltage and current established by the VOLT:TRIG and CURR:TRIG commands. After a *TRG command has been received, subsequent *TRG commands have no effect unless preceded by INIT or INIT:CONT ON. Related Commands: *TRG, TRIG. (See example, Figure B-4.)

B.16 INITiate:CONTinuous COMMAND
Syntax: Short Form: INIT:CONT {ON | OFF} or {1 | 0} (1 = on, 0 = off)
Long Form: INITiate:CONTinuous {ON | OFF} or {1 | 0} (1 = on, 0 = off)
Description: INIT:CONT ON enables continuous triggers.; INIT:CONT OFF disables continuous triggers. If INIT:CONT is OFF, then INIT[:IMM] arms the trigger system for a single trigger. If INIT:CONT is ON, then the trigger system is continuously armed and INIT[:IMM] is redundant. Executing *RST command sets INIT:CONT to ON. (See example, Figure B-4.)

B.17 INITiate:CONTinuous QUERY
Syntax: Short Form: INIT:CONT? Long Form: INITiate:CONTinuous?
Return Value: 1 or 0
Description: Determines whether continuous triggers are enabled or disabled. Power supply returns value of INIT:CONT flag: “1” = continuous triggers are enabled (INIT:CONT ON); “0” = continuous triggers disabled (INIT:CONT OFF). (See example, Figure B-4.)

B.18 MEASure[:SCALar]:CURRent[:DC]? QUERY
Syntax: Short Form: MEAS[:SCAL]:CURR[:DC]?
Long Form: MEASure[:SCALar]:CURRent[:DC]?
Return Value: <num_value> (digits with decimal point and Exponent)
Description: Measures actual current. This query returns the actual value of output current (measured at the output terminals) as determined by the programmed value of voltage and current and load conditions. (See example, Figure B-4.)

B.19 MEASure[:VOLTage][:SCALar][:DC]? QUERY
Syntax: Short Form: MEAS[:SCAL]:VOLT[:DC]?
Long Form: MEASure[:SCALar]:VOLTage[:DC]?
Return Value: <num_value> (digits with decimal point and Exponent)
Description: Measures actual voltage. This query returns the actual value of output voltage (measured at the output terminals) as determined by the programmed value of voltage and current and load conditions. (See example, Figure B-4.)

B.20 OUTPUT[:STATe] COMMAND
Syntax: Short Form: OUTP[:STAT] <boolean>  Long Form: OUTPUT[:STATe] <boolean>
<boolean>=(0 or OFF, 1 or ON)
Description: Enables or disables the power supply output. Upon power up the power supply is in Local mode: the output is always on and the front panel controls affect the unit's operation. Upon entering Remote mode, the default state is OUTP OFF; OUTP ON must be executed to enable the output. When OUTP OFF is executed, the programmed values of voltage and current are saved, then voltage and current are programmed to 0. When OUTP ON is executed, the power supply output is restored to the previously saved programmed values. The saved values of voltage and current can be viewed by VOLT? and CURR? queries. Related Commands: OUTP?

B.21 OUTPUT[:STATe] QUERY
Syntax: Short Form: OUTP[:STAT]?
Long Form: OUTPUT[:STATe]?
Return Value: <int_value> (0 or 1)
Description: Indicates whether power supply output is enabled or disabled. Returns 0 if output disabled, returns 1 if output enabled. Related Commands: OUTP.
B.22 [SOURce:]FUNCtion:MODE COMMAND

**FUNC:MODE**

**Syntax:** Short Form: FUNC:MODE (VOLT | CURR) Long Form: [SOURce:]FUNCtion:MODE (VOLT | CURR)

**Description:** Establishes the operating mode of the power supply. VOLT = Voltage mode. CURR = Current mode. FUNC:MODE VOLT commands power supply to Voltage mode, FUNC:MODE CURR commands power supply to Current mode. Commanded mode establishes parameters (voltage or current) monitored for error conditions. Actual mode depends upon load conditions. When commanded to Voltage mode, if load conditions cause the power supply to try to exceed the current limit, the unit will flag an error condition. When commanded to Current mode, if load conditions cause the power supply to try to exceed the voltage limit, the unit will flag an error condition. If VOLT:MODE or CURR:MODE is set to TRANS, FUNC:MODE command automatically changes the mode to FIXed. (See example, Figure B-4.)

B.23 [SOURce:]FUNCtion:MODE? QUERY

**FUNC:MODE?**

**Syntax:** Short Form: FUNC:MODE? Long Form: [SOURce:]FUNCtion:MODE?

**Return Value:** 0 (voltage mode) or 1 (current mode)

**Description:** Returns the operating mode of the power supply. 0 = Voltage mode. 1 = Current mode.

B.24 [SOURce:]FUNCtion:MODE:TRIGger

**FUNC:MODE:TRIG**

**Syntax:** Short Form: FUNC:MODE:TRIG (VOLT | CURR) Long Form: [SOURce:]FUNCtion:MODE:TRIGger (VOLT | CURR)

**Description:** Establishes the operating mode of the power supply when a TRIGger command is sent. VOLT = Voltage mode. CURR = Current mode. This command establishes the operating mode for triggers which is to be saved or recalled using *SAV or *RCL command. FUNC:MODE:TRIG VOLT commands power supply to Voltage mode when a TRIGger command is sent, FUNC:MODE:TRIG CURR commands power supply to Current mode when a TRIGger command is sent. If VOLT:MODE or CURR:MODE is set to TRANS, FUNC:MODE:TRIG command automatically changes the mode to FIXed. (See example, Figure B-5.)

B.25 [SOURce:]FUNCtion:MODE:TRIGger? QUERY

**FUNC:MODE:TRIG?**

**Syntax:** Short Form: FUNC:MODE:TRIG? Long Form: [SOURce:]FUNCtion:MODE:TRIGger?

**Return value:** 0 = voltage mode or 1 = current mode

**Description:** Returns the operating mode which the power supply will enter when a trigger command is sent. VOLT = Voltage mode. CURR = Current mode. (See example, Figure B-5.)

B.26 [SOURce:]LIST:CLEar COMMAND

**LIST:CLE**

**Syntax:** Short Form: LIST:CLE Long Form: LIST:CLEar>

**Description:** Clears all list entries by setting all pointers to 0. Also sets LIST:DIR to UP, LIST:GEN to DSEQ and LIST:COUNT to 1. Related Commands: All LIST commands (See example, Figures B-2 and B-3.)

B.27 [SOURce:]LIST:COUNt COMMAND

**LIST:COUN**

**Syntax:** Short Form: LIST:COUN<int_value 0 to 255> Long Form: LIST:COUNt> <int_value 0 to 255>

**Description:** Establishes how many times the list is executed. Allows user to establish how many times the list (established by LIST:GEN DSEQ or LIST:GEN SEQ and LIST:SEQ) is executed. The order (from beginning to end or from end to beginning) is determined by LIST:DIR. For LIST:COUN 0, the unit will execute the sequence indefinitely until either a VOLT:MODE FIXED, or PROG:STOP command is received. Commands: LIST:GEN, LIST:SEQ, LIST:DIR. (See example, Figures B-2 and B-3.)

B.28 [SOURce:]LIST:COUNt? QUERY

**LIST:COUN?**

**Syntax:** Short Form: LIST:COUN? Long Form: LIST:COUNt?

**Return Value:** <int_value>

**Description:** Identifies how many times the list will be executed. Returns value set by LIST:COUN command. (See example, Figure B-3.)
B.29 [SOURce:]LIST:COUN:SKIP COMMAND

**LIST:COUN:SKIP**

**Syntax:**
- Short Form: LIST:COUN:SKIP nn
- Long Form: LIST:COUN:SKIP nn

**Description:**
Allows beginning steps of list-generated waveform to be run once, then ignored.

When a list is to be repeated using LIST:COUNT, this command allows the user to skip the first nn steps once the full set has been executed. After the first iteration (which executes all steps), the first nn steps are skipped. The LIST:COUN:SKIP command allows the user to precondition a list-generated waveform by setting unique conditions at the beginning that are not repeated for the rest of the repetitions. LIST:CLEar sets nn to 0. Only works in LIST:DIR UP mode; if LIST:DIR DOWN is issued, this command has no effect. Related Commands: LIST:COUN, LIST:COUN:SKIP?, LIST:SEQ, LIST:DIR, LIST:CLE. (See example, Figures B-2 and B-3.)

B.30 [SOURce:]LIST:COUN:SKIP? QUERY

**LIST:COUN:SKIP?**

**Syntax:**
- Short Form: LIST:COUN:SKIP?
- Long Form: LIST:COUN:SKIP?

**Return Value:** <int_value>

**Description:**
Identifies how many steps will be skipped the first time the list is executed. Returns value set by LIST:COUN:SKIP command. (See examples, Figure B-3.)

B.31 [SOURce:]LIST:CURRent COMMAND

**LIST:CURR**

**Syntax:**
- Short Form: LIST:CURR <exp_value>, <exp_value>, . . . (to max of 1002 data points)
- Long Form: LIST:CURRent <exp_value>, <exp_value>, . . . (to max of 1002 data points)

**<exp_value>** = digits with decimal point and Exponent, e.g., 2.71E1 for 27.1

**Description:**
Adds the current value (in Amps) to list. This command sequentially adds LIST:CURRent values to the main channel List Data Table locations illustrated in Table B-2. Starting location is indicated by LIST:POINt? These locations correspond to the default sequence (LIST:GEN DESQ). The maximum number of entries is 1002. Since the input buffer of the BIT 802E has a limit of 253 characters, multiple commands are necessary to complete the full 1002 entries of the list. If LIST:VOLT has any entries, an error message: -221,“Settings conflict” is posted in the error queue. Related Commands: LIST:CURR:POINt?. (See example, Figure B-3.)

<table>
<thead>

</tbody>
</table>

B.32 [SOURce:]LIST:CURRent? QUERY

**LIST:CURR?**

**Syntax:**
- Short Form: LIST:CURR? Long Form: LIST:CURR?

**Return Value:** <value1>, <value2>, . . . to <value16>

**Description:**
Identifies the parameters (main channel) entered for the list. Starting at location established by LIST:QUERY, returns comma-separated list of up to 16 values indicating the main channel parameters entered, i.e., the contents of main channel locations of Table B-2. Related Commands: LIST:CURR, LIST:QUERY. If LIST:VOLT has any entries, an error message: -221,“Settings conflict” is posted in the error queue. (See example, Figure B-3.)

B.33 [SOURce:]LIST:CURRent:POINts? QUERY

**LIST:CURR:POINt?**

**Syntax:**
- Short Form: LIST:CURR:POINt? Long Form: LIST:CURRent:POINt?

**Return Value:** <value> (0 to 1001)

**Description:**
Identifies the total number of points in a list and the next location to be filled by LIST:CURR command. The LIST:CURR pointer is initially at 0 via LIST:CLE. For each data point entered by a LIST:CURR command the list pointer is incremented. If LIST:CURR:POINt? returns 5, the LIST:CURR pointer is at 5, indicating there are 6 data points comprising the list. If LIST:VOLT has any entries, an error message: -221,“Settings conflict” is posted in the error queue. Related Commands: LIST:CURR. (See example, Figure B-3.)
B.34 [SOURce:]LIST:DIRection COMMAND
Syntax: Short Form: LIST:DIR (UP|DOWN) Long Form: LIST:DIRection (UP|DOWN)
Description: Allows the list to be executed from beginning to end (UP) or from end to the beginning (DOWN). *RST or LIST:CLEar sets the list to the UP direction (beginning to end). Works with both LIST:GEN DSEQ and LIST:GEN SEQ commands. Related Commands: LIST:GEN, LIST:SEQ, LIST:DWEL?. (See example, Figures B-2 and B-3.)

B.35 [SOURce:]LIST:DIRection? QUERY
Syntax: Short Form: LIST:DIR? Long Form: LIST:DIRection?
Return Value: <value> (UP or DOWN)
Description: Identifies the direction (up or down) for executing the list established by LIST:DIR. Related Commands: LIST: DIR. (See example, Figure B-3.)

B.36 [SOURce:]LIST:DWELl COMMAND
Syntax: Short Form: LIST:DWEL <value> (0.0005 to 10),<value>,<value>, . . . to maximum of 1002 values Long Form: LIST:DWELl <value> (0.0005 to 10),<value>,<value>, . . . to maximum of 1002 values
Description: Determines how long the main channel parameters will be active. Sets time value (from 0.0005 to 10) in seconds for List:Dwell locations illustrated in Table B-2. These locations are associated with the corresponding main channel locations illustrated in Table B-2. The main channel is determined by FUNC:MODE, either current (FUNC:MODE CURR) or voltage (FUNC:MODE VOLT) If LIST:DWEL is entered for only location 0, that time duration will apply to all steps when either VOLT:MODE LIST or CURR:MODE LIST is executed. Related Commands: VOLT:MODE, FUNC:MODE, LIST:CURR, LIST:VOLT, LIST:DWEL?, LIST:SEQ. (See example, Figures B-2 and B-3.)

B.37 [SOURce:]LIST:DWEL? QUERY
Syntax: Short Form: LIST:DWEL? Long Form: LIST:DWEL?
Return Value: <value>
Description: Identifies the dwell times entered for the list. Starting at location established by LIST:QUERY, returns comma-separated list of up to 16 values indicating the dwell time parameters entered. i.e., the contents of LIST:DWEL locations of Table B-2. Related Commands: LIST: DWEL, LIST:QUERY. (See example, Figure B-3.)

B.38 [SOURce:]LIST:DWEL:POINts? QUERY
Syntax: Short Form: LIST:DWEL:POIN? Long Form: LIST:DWEL:POINt?
Return Value: <value> (0 to 1001)
Description: Identifies the number of locations for which time values have been entered and the next location to be filled by a LIST:DWEL command. If LIST:DWEL:POIN? returns 6, dwell times have been entered for locations 0 through 5 and location 6 is the next to be filled by a LIST:DWEL command. LIST:DWEL, LIST:DWEL:POIN. (See example, Figure B-3.)
**SIMPLE STAIRCASE SAWTOOTH WAVEFORM EXAMPLE**

* RST
  Resets power supply to the default state.

CURR 1
  Sets programmed current to 1A.

LIST:CLE
  Clears all list entries by setting all pointers to 0.

LIST:VOLT -5,-4,-3,-2,-1,0,1,2,3,4,5
  Create 10 steps that increases from -5V to +5V.

LIST:DWEL 2
  Set the dwell time for each step to 2 seconds.

LIST:COUN 10
  Determines that the list will be repeated 10 times when executed.

OUTP ON
  Turns the BOP output on.

VOLT:MODE LIST
  Initiates execution of the list.

Upon sending VOLT:MODE LIST, the unit outputs a sawtooth waveform that increases from -5V to +5V and repeats 10 times. Each step is 1V with a dwell time of 2 seconds. There is an abrupt change from +5V to -5V each time the list transitions from the last step to the first step of the waveform. After the waveform repeats 10 times, the list stops running and the unit output will be +5V (the last step in the list). The total list running time is equal to:

10 (from LIST COUN) x 11 (total number of list steps) x 2 seconds (dwell time of each step) = 220 seconds

To invert the waveform, when the list stops running, add the following command between OUTP ON and VOLT:MODE LIST above.

LIST:DIR DOWN
  List direction is from the end to the beginning of the list.

Upon sending VOLT:MODE LIST, the unit outputs an inverted sawtooth waveform that is similar to the non-inverted waveform, except it decreases from +5V to -5V and abruptly returns to +5V. After the waveform repeats 10 times, the list stops running and the unit output will be -5V (the first step in the list, and the last step executed). The total list running time is the same as before the direction was reversed.

**SIMPLE STAIRCASE TRIANGLE WAVEFORM EXAMPLE**

* RST
  Resets power supply to the default state

CURR 1
  Sets programmed current to 1A

LIST:CLE
  Clears all list entries by setting all pointers to 0.

LIST:VOLT 0,1,2,3,4,5,6,7,8,9,10
  Create 11 steps that increase from 0V to +10V.

LIST:VOLT 9,8,7,6,5,4,3,2,1,0
  Create 10 steps that decrease from +9V to 0V. The 21-step list forms a triangle stair waveform that first increases from 0V to +10V and then decreases to 0V.

LIST:DWEL 2
  Sets the dwell time for each step to 2 seconds.

LIST:COUN 10
  Determines that the list will be repeated 10 times when executed.

OUTP ON
  Turns the BOP output on

VOLT:MODE LIST
  Initiates execution of the list.

The unit outputs a triangle stair waveform, that increases from 0V to +10V and then decrease to 0V. The waveform repeats 10 times. Each step is 1V with a dwell time of 2 seconds. The waveform stays at 0V for 4 seconds because for each repetition, the last step of the decreasing list and the first step of the increasing list are both 2 seconds at 0V. When the list stops running, the output will be 0V (the last step of the list). The total list running time is equal to:

10 (from LIST COUN) x 21 (total number of list steps) x 2 seconds (dwell time of each step) = 420 seconds

To eliminate the first step and make the waveform times even, when the list stops running, add the following command between OUTP ON and VOLT:MODE LIST above.

LIST:COUN:SKIP 1
  Skip first step (0V level) after the first iteration

Upon sending VOLT:MODE LIST, the unit outputs a triangle stair waveform, that is identical to the original, except that the first step (0V) is only executed for the first iteration. After 10 repetitions the list stops running and the output is 0V. The total list running time is equal to:

10 (from LIST COUN) x 20 (total number of repeated list steps) x 2 seconds (dwell time of each step) = 400 seconds + 2 seconds (dwell time of first step, run only once) = 402 seconds.
NOTES: Examples below are intended only to illustrate command functions. Refer to PAR. 4.5.2 for programming techniques to optimize performance.

**FUNC:MODE VOLT**
Initializes the power supply mode to be voltage.

**LIST:CLEAR**
Initializes the list processor to add entries, clears main channel (LIST:CURR or LIST:VOLT) and LIST:DWEL data tables (Table B-2) and List Sequence table (Table B-3).

**LIST:DWELL .010**
Sets the time duration for location 0 to be 0.010 second (Since dwell times for the rest of the locations in this sample list are not entered before running the list, the dwell time will be 0.010 second for all locations.

**LIST:VOLT -20,-18,-16,-14,-12,-10,-8,-6,-4,-2,0**
Starting at location 0 (-20), up to location 10 (0), fills the list with 11 data points.

**LIST:VOLT:POIN?**
Returns 11. Indicates that 11 data points have been entered, and location 11 is the next location to be filled (for the 12th data point).

**NOTE:** See PAR. B.2 for format and accuracy of all numerical data returned.

**LIST:QUERY?**
Returns 0 (pointer cleared by LIST:CLE).

**LIST:VOLT?**
Returns -20,-18,-16,-14,-12,-10,-8,-6,-4,-2,0 (the contents of locations 0 through 10). (See PAR. B.2 for format and accuracy of numerical data.)

**LIST:VOLT 2,4,6,8,10,12,14,16,18,20**
Adds 10 points to the list (location 11 through 20). List now has 21 points.

**LIST:VOLT:POIN?**
Returns 21 (the next location to be filled by LIST:VOLT).

**LIST:VOLT?**
Returns -20,-18,-16,-14,-12,-10,-8,-6,-4,-2,0,2,4,6,8 (the contents of locations 0 through 15).

**LIST:GEN SEQUENCE**
Enables the execution of a user-determined sequence list

**LIST:SEQ 0, 0, 0, 0,1,2,3,4,5,6,7,8,9,10,11,12,13,14,15,16,17,18,19,20**
Establishes the user-determined sequence.

**LIST:SEQ 19,18,17,16,15,14,13,12,11,10,9,8,7,6,5,4,3,2,1,0**
Continues the user-determined list sequence. The SEQ values entered mean that if LIST:GEN SEQ is issued, the list will execute location 0 four times (-20V for 40 milliseconds) location 1 through 20 and 19 through 0 (10 milliseconds each) for a total of 44 data points when VOLT:MODE LIST is issued.

**LIST:SEQ?**
Returns 0,0,0,0,1,2,3,4,5,6,7,8,9,10,11,12 (LIST:SEQ locations 0 through 15).

**LIST:QUERY 16**
Start LIST queries from location 16.

**LIST:SEQ?**
Returns 13,14,15,16,17,18,19,20,19,18,17,16,15,14,13,12 (LIST:SEQ locations 16 through 31).

**LIST:QUERY 32**
Start LIST queries from location 32.

**LIST:SEQ?**
Returns 11,10,9,8,7,6,5,4,3,2,1,0 (LIST:SEQ locations 32 through 43).

**LIST:COUN 100**
Specifies that when VOLT:MODE LIST is issued, the user-determined sequence will be executed 100 times. (44 steps in the list will be executed 100 times)

**LIST:COUN:SKIP 4**
Specifies that the first 4 steps of the sequence will only be executed the first time through the list. For the subsequent 99 iterations established by LIST:COUN 100, location 0 (-20V) will last 10 milliseconds.

**CURR 1;VOLT -20**
Initializes the BOP output.

**OUTPUT ON**
Turns the output on (BOP now provides -20 volts)

**VOLT:MODE LIST**
Executes the list. For 40 milliseconds the BOP outputs -20V, then output a staircase triangle wave from -20V to +20V and back down to -20V. This staircase will have a uniform spacing between voltage changes of 10 milliseconds and will repeat 100 times.

**VOLT?**
Returns -20 (the last step in the list set the unit to -20V.

**LIST:GEN?**
Returns SEQ to indicate the list will be executed in the user-determined order entered by LIST:SEQ (Table B-3).

---

**FIGURE B-3. USING LIST COMMANDS AND QUERIES (SHEET 2 OF 2)**
B.39 [SOURce:]LIST:GENeration COMMAND

**LIST:GEN**

Syntax: Short Form: LIST:GEN (SEQ | DSEQ)
Long Form: LIST:GENeration (SEQuence | DSEQ)

Description: Establishes the order for executing the list. Selects either default sequence (DSEQ) or a user-determined sequence (SEQ).

DSEQ is the default sequence shown in Table B-2 and Table B-3, 0 through 1001. When LIST:GEN DSEQ is issued, the data points are executed in order either from beginning (location 0) to end (the last location with data, up to location 1001), or from end to beginning (location 0). The order is established by LIST:DIR command.

SEQ allows the list to be executed by an arbitrary sequence (up to 512 steps) determined by LIST:SEQ and LIST:DIR. Related Commands: LIST:SEQ, LIST:DIR. (See example, Figure B-3.)

B.40 [SOURce:]LIST:GENeration? QUERY

**LIST:GEN?**

Syntax: Short Form: LIST:GEN? Long Form: LIST:GENeration?

Return Value: <value> (SEQ or DSEQ)

Description: Identifies the sequence for executing the list. Returns DSEQ for the default sequence, SEQ for user determined sequence. Related Commands: LIST:GEN. (See example, Figure B-3.)

B.41 [SOURce:]LIST:QUERy COMMAND

**LIST:QUER**

Syntax: Short Form: LIST:QUER <int_value>
Long Form: LIST:QUERy <int_value>

int_value = 0 to 1001

Description: Determines first location to be queried by LIST:SEQ? query. Related Commands: LIST:SEQ?, LIST:QUER?. (See example, Figure B-3.)

B.42 [SOURce:]LIST:QUERy? QUERY

**LIST:QUER?**

Syntax: Short Form: LIST:SEQ? Long Form: LIST:SEQ?

Return Value: <value1>, <value2>, . . . to <value16>

Description: Identifies the user-determined sequence for executing the list. Starting at location established by LIST:QUER, returns comma-separated list of up to 16 values indicating the user-determined sequence for executing the list, i.e., the contents of the SEQ locations of Table B-3. Related Commands: LIST:SEQ, LIST:QUER. (See example, Figure B-3.)

---

**TABLE B-3. LIST SEQUENCE TABLE**

B.43 [SOURce:]LIST:SEQuence COMMAND

Syntax: Short Form: LIST:SEQ <int_value>, <int_value>, etc. to max. of 512 locations
Long Form: LIST:SEQence <int_value>, <int_value>, etc. to max. of 512 locations

int_value = 0 to 511

Description: Determines the order to execute data points of the list when LIST:GEN SEQ is issued. The LIST:SEQ command is provided for backward compatibility. It is not recommended to be used in any new designs as it may be eliminated at some point in the future. Integer values fill the SEQ cells of the List Sequence Table (see Table B-3) in order, starting at location 0. For example, for a list with five points, if LIST:SEQ 4,2,1,3,0 is followed by LIST:GEN SEQ, the list will start from data point 4 (see Table B-2), then execute points 2, 1, 3, 0. (On the other hand, if LIST:GEN DSEQ is issued, data points are executed sequentially starting at 0, then 1, 2, 3, 4.) SEQ steps can be arranged to repeat steps in any order; for example a 17-step sequence for a list having five data points may be as follows: LIST SEQ 0,1,2,3,4,5,4,3,2,1,0,1,5,5,5,1,1,1. Related Commands: LIST:GEN, LIST:DIR, LIST:COUN, LIST:COUN:SKIP. (See example, Figure B-3.)

B.44 [SOURce:]LIST:SEQuence? QUERY

**LIST:SEQ?**

Syntax: Short Form: LIST:SEQ? Long Form: LIST:SEQquence?

Return Value: <value1>, <value2>, . . . to <value16>

Description: Identifies the user-determined sequence for executing the list. Starting at location established by LIST:QUERY, returns comma-separated list of up to 16 values indicating the user-determined sequence for executing the list, i.e., the contents of the SEQ locations of Table B-3. Related Commands: LIST: SEQ, LIST:QUERy. (See example, Figure B-3.)
B.45 **[SOURce:]LIST:VOLTage** COMMAND

**LIST:VOLT**

Short Form: LIST:VOLT[:LEV] <exp_value>, <exp_value>, . . . (to max of 1002 data points)
Long Form: LIST:VOLTage[:LEVel] <exp_value>, <exp_value>, . . . (to max of 1002 data points)
<exp_value> = digits with decimal point and Exponent, e.g., 2.71E1 for 27.1

Description: **Adds the voltage value (in Volts) to list.** This command sequentially adds LIST:VOLTage values to the main channel List Data Table locations illustrated in Table B-2. LIST:CLE sets starting location to 0. Next location indicated by LIST:VOLT:POIN? These locations correspond to the default sequence (LIST:GEN DESQ) The maximum number of entries is 1002. Since the input buffer of the BIT 802E has a limit of 253 characters, multiple commands are necessary to complete the full 1002 entries of the list. If LIST:CURR has any entries, an error message: -221,"Settings conflict" is posted in the error queue. Related Commands: LIST:VOLT:POIN?, FUNC:MODE, LIST:CLE, *RST. (See example, Figures B-2 and B-3.)

B.46 **[SOURce:]LIST:VOLTage?** QUERY

**LIST:VOLT?**

Syntax: Short Form: LIST:VOLT? Long Form: LIST:VOLTage?
Return Value: <value1>, <value2>, . . . to <value16>

Description: **Identifies the parameters (main channel) entered for the list.** Starting at location established by LIST:QUERY, returns comma-separated list of up to 16 values indicating the main channel parameters entered. i.e., the contents of the main channel locations of Table B-2. Related Commands: LIST:VOLT, LIST:QUEry. If LIST:CURR has any entries, an error message: -221,"Settings conflict" is posted in the error queue. (See example, Figure B-3.)

B.47 **[SOURce:]LIST:VOLTage:POINts?** QUERY

**LIST:VOLT:POIN?**

Return Value: <value> (0 to 1001)

Description: **Identifies the total number of points in a list and the next location to be filled by LIST:VOLT command.** The LIST:VOLT pointer is initially at 0 via *RST or LIST:CLE. For each data point entered by a LIST:VOLT command the list pointer is incremented If LIST:VOLT:POIN? returns 5, the LIST:VOLT pointer is at 5 indicating there are 5 data points comprising the list (locations 0 though 4) and location 5 is the next to be filled. If LIST:CURR has any entries, an error message: -221,"Settings conflict" is posted in the error queue. Related Commands: LIST:VOLT. (See example, Figure B-3.)

B.48 **[SOURce:]CURRent[:LEVel][:IMMediate][:AMPlitude]** COMMAND

**CURR**

Syntax: Short Form: [SOUR:]CURR[:LEV][:IMM][:AMP] <exp_value>
Long Form: [SOURce:]CURRent[:LEVel][:IMMediate][:AMPlitude] <exp_value>
<exp_value> = digits with decimal point and Exponent, e.g., 2.71E1 for 27.1

Description: **Sets programmed current level at power supply output.** This command programs output current to a specific value; actual output current will depend on load conditions. If CURR:RANG is set to 4, any data that exceeds 1/4 of I MAX causes error message -222 "data out range" to be posted to the error queue (See example, Figure B-4.)

B.49 **[SOURce:]CURRent[:LEVel][:IMMediate][:AMPlitude]** QUERY

**CURR?**

Syntax: Short Form: [SOUR:]CURR[:LEV][:IMM][:AMP] MIN, MAX
Long Form: [SOURce:]CURRent[:LEVel][:IMMediate][:AMPlitude] MIN, MAX
Return Value:<exp_value> = digits with decimal point and Exponent, e.g., 2.71E1 for 27.1

Description: **Returns either the programmed value, maximum value, or minimum value of current.** The CURR? query returns the programmed value of current. Actual output current will depend on load conditions. The CURR?MAX query returns the maximum current allowed for a particular model. CURR? MIN returns minimum current allowed for power supply (always negative). Related Commands: CURR. (See example, Figure B-4.)
Figure B-4. Programming the Output

B.50 \texttt{[SOURce:]CURRent:MODE COMMAND}

Syntax: \texttt{[SOUR:]}\texttt{CURR:MODE (FIX | LIST | TRAN) nn}
\texttt{[SOURce:]CURR:MODE (FIXed | LIST | TRANsient) nn}
\texttt{nn = <value> = time in seconds for transient}

Description: \textbf{Allows the user to execute or stop a list, or to execute a transient.} The default mode is FIXed: the power supply executes commands normally, and LIST commands can be issued to establish the parameters and sequence of a list.

When \texttt{CURR:MODE LIST} is issued, a list is executed (See LIST commands and Figure B-3). While the list is being executed, LIST commands are not accepted and will produce a command error. Issuing \texttt{CURR:MODE FIX} while the list is running will stop the execution of the list and return power supply to settings in effect prior to running the list. If the list runs to completion, the settings of the last step of the list will be in effect.

\texttt{CURR:MODE TRANs nn} causes the next \texttt{CURR:} command to produce a transient pulse of \texttt{nn} seconds duration, after which the current reverts back to the previous setting (Similar to \texttt{VOLT:MODE TRANs} (see \texttt{PAR. B.59} for examples). If the time \texttt{nn} exceeds 10 seconds, error message -222 “data out range” is posted to the error queue. \textbf{Related Commands:} LIST commands. (See example, Figures B-2 and B-3.)

\textbf{NOTES:}
1. The power supply is assumed to be operating in Voltage mode.
2. Examples below are intended only to illustrate command functions. Refer to \texttt{PAR. 4.5.2} for programming techniques to optimize performance.

</tbody>
</table>
B.51 [SOURce:]CURRent:MODE? QUERY

Syntax: Short Form: [SOUR:]CURR[:LEV]:MODE?  
Long Form: [SOURce:]CURRent[:LEVel]:MODE?

Return value: FIXED or LIST or TRANS

Description: Identifies active current mode. Returns LIST while list is being executed. Returns TRANSIENT after CURR:MODE:TRAN command has been issued, but before CURR: or *TRG command executes the transient. Returns FIXED while in fixed (default) mode of operation. Related Commands: LIST commands. (Similar to VOLT:MODE?, see Figure B-3.)

B.52 [SOURce:]CURRent[:LEVel]:RANGe COMMAND

Syntax: Short Form: [SOUR:]CURR[:LEV]:RANG <value>  
Long Form: [SOURce:]CURRent[:LEVel]:RANGe <value>

<value> = 1 (full scale) or 4 (1/4 scale)

Description: Allows the user to specify the operating range for control of output current. Range = 1 allows control of output current from 0 to full scale. Range = 4 allows the full range of the 16 bit D to A converter to control 1/4 of the full scale output current. This command will generate a command warning error if the unit is not in current mode. It will be remembered until a func:mode command is processed. (See example, Figure B-4.)

B.53 [SOURce:]CURRent[:LEVel]:RANGe? QUERY

Syntax: Short Form: [SOUR: CURR[:LEV]:RANG?  
Long Form: [SOURce:]CURRent[:LEVel]:RANGe?

Description: Identifies programmed current range. Returns 1 (full scale) or 4 (1/4 scale) (See example, Figure B-4.)

B.54 [SOURce:]CURRent[:LEVel]:RANGe:AUTO COMMAND

Syntax: Short Form: [SOUR:]CURR[:LEV]:RANG:AUTO <boolean>  
Long Form: [SOURce:]CURRent[:LEVel]:RANGe:AUTO <boolean>

<boolean> = 1 (on) or 0 (off)

Description: Allows the user to specify automatic range for control of output voltage or current. Upon power up or upon receiving *RST, automatic ranging is selected. Automatic ranging can be turned off by VOLT:RANG:AUTO 0, CURR:RANG:AUTO 0, VOLT:RANG 1 or 4, or CURR:RANG 1 or 4. When automatic ranging is set, the correct range is automatically selected based on the programmed parameter. If the programmed parameter is more than 1/4 of nominal full scale, full scale is selected; if equal to or less than 1/4 of full scale, the 1/4 scale range is selected. For example, if auto ranging is set for a unit with 100V nominal output operating in voltage mode, a programmed voltage of up to 25.0V automatically selects range to 1/4 scale, while programming anything above 25.0V selects full scale. Function is identical to VOLT:RANG:AUTO.

B.55 [SOURce:]CURRent[:LEVel]:TRIGgered[:AMPlitude] COMMAND

Syntax: Short Form: [SOUR:]CURR[:LEV]:TRIG[:AMP] <exp_value>  
Long Form: [SOURce:]CURRent[:LEVel]:TRIGgered[:AMPlitude] <exp_value>

<exp_value> = digits with decimal point and Exponent, e.g., 2.71E1 for 27.1

Description: Programs current value to be transferred to output by *TRG or TRIG commands. This command can be used to reset many power supplies to preselected parameters by issuing a single *TRG or TRIG command. Actual output current will depend on load conditions. If the value exceeds the maximum for the model being programmed, error message -222,”Data out of range” is posted in output queue. Related Commands: CURR, *TRG, TRIG (See example, Figure B-5.)

B.56 [SOURce:]CURRent[:LEVel]:TRIGgered[:AMPlitude]? QUERY

Syntax: Short Form: [SOUR:]CURR[:LEV]:TRIG[:AMP]?  
Long Form: [SOURce:]CURRent[:LEVel]:TRIGgered[:AMPlitude]?

Return Value: <exp_value> = digits with decimal point and Exponent, e.g., 2.71E1 for 27.1

Description: Returns the current value established by CURR:TRIG command. (See example, Figure B-5.)
NOTES: 1. The power supply is assumed to be operating in Voltage mode.
2. Examples below are intended only to illustrate command functions. Refer to PAR. 4.5.2 for programming techniques to optimize performance.

B.57 [SOURce:] VOLTage[:LEVel][:IMMediate][:AMPplitude] COMMAND

Syntax: Short Form: [SOUR]: VOLT[:LEV][:IMM][:AMP] <exp_value>
Long Form: [SOURce:] VOLTage[:LEVel][:IMMediate][:AMPplitude] <exp_value>
<exp_value> = digits with decimal point and Exponent, e.g., 2.71E1 for 27.1

Description: Sets programmed voltage level at power supply output. This command programs output voltage to a specific value; actual output voltage will depend on load conditions. If the value exceeds the maximum for the model being programmed, error message -222, "Data out of range" is posted in output queue. (See example, Figure B-4.)

B.58 [SOURce:] VOLTage[:LEVel][:IMMediate][:AMPplitude]? QUERY

Syntax: Short Form: [SOUR]: VOLT[:LEV][:IMM][:AMP]? {MIN | MAX}
Long Form: [SOURce:] VOLTage[:LEVel][:IMMediate][:AMPplitude]? {MIN | MAX}

Description: Identifies programmed voltage, maximum allowable voltage, or minimum voltage (always 0). The VOLT? query returns the programmed value of voltage. Actual output voltage will depend on load conditions. The VOLT?MAX query returns the maximum voltage allowed for a particular model. VOLT? MIN returns minimum voltage allowed for power supply (always negative). Related Commands: VOLT. (See example, Figure B-4.)

B.59 [SOURce:] VOLTage:MODE COMMAND

Syntax: Short Form: [SOUR]: VOLT:MODE (FIX | LIST | TRAN) nn
Long Form: [SOURce:] VOLTage:MODE (FIXed | LIST | TRANsient) nn
nn = <value> = time in seconds for transient

Description: Allows the user to execute or stop a list, or to execute a transient. The default mode is FIXed: the power supply executes commands normally, and LIST commands can be issued to establish the parameters and sequence of a list.

When VOLT:MODE LIST is issued, a list is executed (See LIST commands and Figure B-3). While the list is being executed, LIST commands are not accepted and will produce a command error. Issuing VOLT:MODE FIX while the list is running will stop the execution of the list and return power supply to settings in effect prior to running the list. If the list runs to completion, the settings of the last step of the list will be in effect.

VOLT:MODE TRANs nn causes the next VOLT: command to produce a transient pulse of nn seconds duration, after which the voltage reverts back to the previous setting. E.g., VOLT:25 sets the output to 25 volts, and VOLT:MODE TRAN .02 primes the unit for a transient of 0.02 seconds. When
VOLT:10 is issued, the power supply output goes to 10V for 0.02 seconds, then reverts to 25V. Similarly, sending VOLT:TRIG 14, VOLT:MODE TRAN .05 and *TRG causes the output to go to 14V for 0.05 seconds, then revert to 25V. Related Commands: LIST commands. (See example, Figures B-2 and B-3.)

B.60 [SOURce:]VOLTage:MODE? QUERY
Syntax: Short Form: [SOUR:]VOLT[:LEV]:MODE?
Long Form: [SOURce:]VOLTage[:LEVel]:MODE?
Return value: FIXED or LIST or TRANS
Description: Identifies active voltage mode. Returns LIST while list is being executed. Returns TRANSIENT after VOLT:MODE TRAN nn command has been issued, but before VOLT: or *TRG command executes the transient. Returns FIXED while in fixed (default) mode of operation. Related Commands: LIST commands. (See example, Figure B-3.)

B.61 [SOURce:]VOLTage[:LEVel]:RANGe COMMAND
Syntax: Short Form: [SOUR:]VOLT[:LEV]:RANG <value>
Long Form: [SOURce:]VOLTage[:LEVel]:RANGe <value>
<value> = 1 (full scale) or 4 (1/4 scale)
Description: Allows the user to specify the operating range for the active mode (either voltage or current). When in voltage mode this command establishes the voltage range, in current mode it establishes the current range. Range = 1 allows control of output voltage or current from 0 to full scale. Range = 4 allows the full range of the 16 bit D to A converter to control 1/4 of the full scale output voltage or current to provide greater accuracy. This command overrides VOLT:RANG:AUTO and turns auto ranging off. (Similar to CURR:RANG? shown in Figure B-4.)

B.62 [SOURce:]VOLTage[:LEVel]RANGe? QUERY
Syntax: Short Form: [SOUR:]VOLT[:LEV]:RANG?
Long Form: [SOURce:]VOLTage[:LEVel]:RANGe?
Return value: 1 (full scale) or 4 (1/4 scale)
Description: Identifies active range. Returns 1 (full scale) or 4 (1/4 scale) (Similar to CURR:RANG? shown in Figure B-4.)

B.63 [SOURce:]VOLTage[:LEVel]:RANGe:AUTO COMMAND
Syntax: Short Form: [SOUR:]VOLT[:LEV]:RANG:AUTO <boolean>
Long Form: [SOURce:]VOLTage[:LEVel]:RANGe:AUTO <boolean>
<boolean> = 1 (on) or 0 (off)
Description: Allows the user to specify automatic range for control of output voltage or current. Upon power up or upon receiving *RST, automatic ranging is selected. Automatic ranging can be turned off by VOLT:RANG:AUTO 0, CURR:RANG:AUTO 0, VOLT:RANG 1 or 4, or CURR:RANG 1 or 4. When automatic ranging is set, the correct range is automatically selected based on the programmed parameter. If the programmed parameter is more than 1/4 of nominal full scale, full scale is selected; if equal to or less than 1/4 of full scale, the 1/4 scale range is selected. For example, if auto ranging is set for a unit with 100V nominal output operating in voltage mode, a programmed voltage of up to 25.0V automatically selects range to 1/4 scale, while programming anything above 25.0V selects full scale. Function is identical to CURR:RANG:AUTO.

B.64 [SOURce:]VOLTage[:LEVel]:TRIGgered[:AMPplitude] COMMAND ?
Syntax: Short Form: [SOUR:]VOLT[:LEV]:TRIG[AMP] <exp_value>
Long Form: [SOURce:]VOLTage[:LEVel]:TRIGgered[:AMPplitude] <exp_value>
<exp_value> = digits with decimal point and Exponent, e.g., 2.71E1 for 27.1
Description: Programs voltage value to be transferred to output by *TRG or TRIG commands. Actual output voltage will depend on load conditions. If the value exceeds the maximum for the model being programmed, error message -222,"Data out of range" is posted in output queue. If value exceeds VOLT:LIM:HIGH value, a value corresponding to the voltage limit will be programmed. (See example, Figure B-5.)
B.65 [SOURce:]VOLTage[:LEVEL]:TRIGgered[:AMPLitude]? QUERY
VOLT:TRIG?
Syntax: Short Form: [SOURce:]VOLTage[:LEVEL]:TRIGgered[:AMPLitude]?
Long Form: [SOURce:]VOLTage[:LEVEL]:TRIGgered[:AMPLitude]?
Return Value: <exp_value> = digits with decimal point and Exponent, e.g., 2.71E1 for 27.1
Description: Returns value established by VOLT:TRIG command representing voltage value to be programmed by *TRG or TRIG command. (See example, Figure B-5.)

B.66 STATus:OPERation:CONDition QUERY
STAT:OPER:COND?
Return Value: <int_value> 0 to 1313 (1 + 32 + 256 + 1024).
Description: Returns the value of the Operation Condition Register (see Table B-4). The Operation Condition Register contains unlatched real-time information about the operating conditions of the power supply. Bit set to 1 = function enabled (active, true); bit reset to 0 = function disabled (inactive, false). (See example, Figure B-6.)

B.67 STATus:OPERation:ENABle COMMAND
STAT:OPER:ENAB
Syntax: Short Form: STAT:OPER:ENAB <int_value> 0 to 1313 (1 + 32 + 256 + 1024)
Long Form: STATus:OPERation:ENABle <int_value> 0 to 1313 (1 + 32 + 256 + 1024)
Description: Sets Operation Enable Register. The Operation Enable Register is a mask for enabling specific bits in the Operation Event Register which will cause the operation summary bit (bit 7) of the Status Byte register to be set. Bit set to 1 = function enabled (active, true); bit reset to 0 = function disabled (inactive, false). The operation summary bit is the logical OR of all the enabled bits in the Operation Event register. (See example, Figure B-6.)

B.68 STATus:OPERation:ENABle? QUERY
STAT:OPER:ENAB?
Return Value: <int_value> 0 to 1313 (1 + 32 + 256 + 1024).
Description: Reads Operation Enable Register (see Table B-4). Returns value of Operation Enable Register bits. Bit set to 1 = function enabled (active, true); bit reset to 0 = function disabled (inactive, false). (See example, Figure B-6.)

B.69 STATus:OPERation[:EVENt]? QUERY
STAT:OPER?
Syntax: Short Form: STAT:OPER[:EVENt]? Long Form: STATus:OPERation[:EVENt]?
Return Value: <int_value> 0 to 1313 (1 + 32 + 256 + 1024).
Description: Indicates changes in conditions monitored by Operational Event Register (see Table B-4). Returns the value of the Operation Event register. The Operation Event register is a read-only register which holds (latches) all events that occur. Reading the Operation Event register clears it. (See example, Figure B-6.)

B.70 STATus:PRESet COMMAND
STAT:PRES
Syntax: Short Form: STAT:PRES Long Form: STATus:PRESets
Description: Disables reporting of all status events. This command sets all bits of the Operation Condition (Table B-4) and Questionable Condition Registers to 0, preventing all status events from being reported. (See example, Figure B-6.)
NOTES:  1. The power supply is assumed to be operating in Voltage mode.
2. Examples below are intended only to illustrate command functions. Refer to PAR. 4.5.2 for programming techniques to optimize performance.

STAT:PRES  Operation Condition and Questionable Condition registers are reset.
STAT:QUES:ENAB 12228  Allows latching of CE and VE bits.
STAT:OPER:ENAB 1280  Mask enabled for CC and CV bits.
INIT:CONT ON  Continuous triggers enabled.
STAT:OPER:COND?  Power supply returns 256 to indicate that power supply is in Voltage mode.
STAT:OPER?  Returns 256, indicating that since the last reading of the Operation Event Register the power supply has entered Voltage mode.
STAT:OPER?  Returns 0 indicating no changes since previous reading of the Operation Event register.
STAT:QUES?  Returns 0 (no questionable conditions occurred since previous reading

--- OVERCURRENT CONDITION OCCURS
SYST:ERR?  Power supply returns 0, “No error” message.
*RST;:VOLT 5;CURR 1;OUTP ON  The BOP is in Voltage mode and delivering 5 Volts.
*ESR?  Bop returns a 0 - all functions are normal.
FUNC:MODE CURR  BOP is in Current mode but Limit Light is on.
*ESR?,STAT:QUES:COND?  BOP returns 8;4097 - Current error.
*ESR?,STAT:QUES?  BOP returns 0;4096 - no new errors, Current Error.
*ESR?,STAT:QUES?  BOP returns 0;0 - no new errors.
MEAS:CURR?,VOLT?  BOP returns 1.0E-4;5.00003E0 - Voltage is 5 volts.

Short is applied to the BOP.

*ESR?,STAT:QUES:COND?  BOP returns 0;1 - Current mode is selected.
MEAS:VOLT?,CURR?  BOP returns 1E-4;1.00003E0 - Current is 1 amperes.
FUNC:MODE VOLT;*ESR?  BOP switches mode, returns 3 - settling.
*ESR?,;STAT:QUES?  BOP returns 8;8194.

Short is removed from the BOP output.

STAT:QUES:COND?  BOP returns 2, Voltage mode operation OK.

FIGURE B-6. USING STATUS COMMANDS AND QUERIES

B.71 STATus:QUEStionable[:EVENT]? QUERY

Syntax: Short Form: STAT:QUES[EVEN]?  Long Form: STATus:QUEStionable[EVEN]?
Return Value: <int_value> actual register value
Description: Indicates the latched condition of the Questionable Event register. Returns the value of the Questionable Event register (see Table B-5). The Questionable Event register is a read-only register which holds (latches) all events. Only bits 13 and 12 are latched in the Status Questionable Event register. Bits 0 and 1 of the Status Questionable Condition Register are not latched in the power supply. Reading the Questionable Event register clears it. (See example, Figure B-6.)
B.72 STATus:QUEStionable:CONDition? QUERY

Return Value: <int_value> actual register value

Description: Returns the value of the Questionable Condition Register (see Table B-5). The Questionable Condition Register contains unlatched real-time information about questionable conditions of the power supply. Bit set to 1 = condition enabled (active, true); bit reset to 0 = condition disabled (inactive, false). Bits 1 or 0 may be both be set, indicating the power supply is settling after a voltage change. (See example, Figure B-6.)

B.73 STATus:QUEStionable:ENABle COMMAND

Syntax: Short Form: STAT:QUES:ENAB <int_value> Long Form: STATus:QUESionable:ENABle <int_value>

Description: Programs Questionable Condition Enable Register (see Table B-5). The Questionable Condition Enable Register determines which conditions are allowed to set the Questionable Condition Register; it is a mask for enabling specific bits in the Questionable Event register that can cause the questionable summary bit (bit 3) of the Status Byte register to be set. The questionable summary bit is the logical OR of all the enabled bits in the Questionable Event register. Bit set to 1 = function enabled (active, true); bit reset to 0 = function disabled (inactive, false). (See example, Figure B-6.)

B.74 STATus:QUEStionable:ENABle? QUERY

Return Value: <int_value> actual register value

Description: Reads Questionable Condition Enable Register (see Table B-5). Power supply returns value of Questionable Condition Enable Register, indicating which conditions are being monitored. Bit set to 1 = function enabled (active, true); bit reset to 0 = function disabled (inactive, false). Related Commands: STAT:QUES?. (See example, Figure B-6.)

B.75 SYSTem:BEEP COMMAND

Syntax: Short Form: SYST:BEEP Long Form: SYSTem:BEEP

Description: Causes the unit to emit a brief audible tone.

B.76 SYSTem:ERRor? QUERY

Syntax: Short Form: SYST:ERR? Long Form: SYSTem:ERRor?

Return Value: <int_value,string>

Description: Posts error messages to the output queue. Returns the next error number followed by its corresponding error message string from the instrument error queue. The error queue is a FIFO (first in, first out) buffer that stores errors as they occur. As it is read, each error is removed from the queue and the next error message is made available. When all errors have been read, the query returns 0,”No error”. If more errors are accumulated than the queue can hold, it will overflow. The oldest errors stay in the queue but the most recent errors are discarded. The last error in the queue will be -350,”Too many errors.” Error messages are defined in Table B-6.

B.77 SYSTem:ERRor:CODE? QUERY

Syntax: Short Form: SYST:ERR:CODE? Long Form: SYSTem:ERRor:CODE?

Description: Returns the three character error code without the ASCII definition string. The error codes are defined in Table B-6 (See example, Figure B-8.)

B.78 SYSTem:ERRor:CODE:ALL? QUERY

Return Value: 

Description: Returns a comma-separated list of all error codes. A maximum of 15 codes will be returned; if the queue is empty, the power supply returns 0.

B.79 SYSTem:PASSword:CENable COMMAND

Syntax: Short Form: SYST:PASS:CEN <val> Long Form: SYSTem:PASSword:CENable <val>

Description: Sets the password enable state if the value matches the current password. This command allows other commands such as DIAG:SAV and CALibrate to operate. To reset forgotten passwords, contact the factory.
B.80 SYSTem:PASSword:CDISable COMMAND
Syntax: Short Form: SYST:PASS:CDIS <val> Long Form: SYSTem:PASSword:CDISable <val>
Description: Clears the password enable state if the <value> matches the current password.

B.81 SYSTem:PASSword:NEW COMMAND
Syntax: Short Form: SYST:PASS:NEW <old password>,<new password>
Long Form: SYSTem:PASSword:NEW <old password>,<new password>
Description: Establishes new password. The old (current) password is checked, then replaced by the new password. (See example, Figure B-8.)

B.82 SYSTem:PASSword:STATe? QUERY
Syntax: Short Form: SYST:PASS:STAT?
Long Form: SYSTem:PASSword:STATe?
Return Value: <int_value> 0 or 1
Description: Returns a 1 if the password state is enabled or a 0 if it is disabled.

B.83 SYSTem:REMote COMMAND
Syntax: Short Form: SYST:REM {ON | OFF} or {1 | 0}
Long Form: SYSTem:REMote {ON | OFF} or {1 | 0}
Description: Used during serial (Telnet) communication to set the unit to remote (1 or ON) or local (0 or OFF) mode. This command must be issued prior to commands that affect the power supply output (e.g., VOLT 10;:OUTP ON) to ensure the unit is in remote mode. See PAR. 4.5 and Figure B-7.

B.84 SYSTem:REMote? QUERY
Syntax: Short Form: SYST:REM?
Long Form: SYSTem:REMote?
Return Value: {1 | 0}
Description: Identifies whether unit it in remote mode (1) or local mode (0) during serial (Telnet) communication. See PAR. 4.5 and Figure B-7.

B.85 SYSTem:SECurity:IMMediate COMMAND
Description: Initializes all NVRAM variables to factory defaults. Empties all memory locations. This command is password protected and requires that SYST:PASS:CEN be issued before sending this command.

*IDN? Unit responds with KEPCO,BOP 20-20,E1234,1.66 (typical).
OUTP? Unit responds with 0 indicating output is off
SYST:REM? Unit responds with 0 indicating unit is in local mode.
SYST:REM 1 PUTS UNIT IN REMOTE MODE.
OUTP ON Enables output
OUTP? Unit responds with 1 (output on).
SYST:REM 0 Unit set to local mode.

FIGURE B-7. SETTING THE UNIT TO REMOTE MODE VIA TELNET
### TABLE B-6. ERROR MESSAGES

<table>
<thead>
<tr>
<th>ERROR MESSAGE</th>
<th>EXPLANATION</th>
</tr>
</thead>
<tbody>
<tr>
<td>0,“No error”</td>
<td>No error</td>
</tr>
<tr>
<td>-100,“Command error”</td>
<td>Command or data that followed command was not understood.</td>
</tr>
<tr>
<td>-109,“Missing Parameter”</td>
<td>Command understood, required information was not included or incorrect.</td>
</tr>
<tr>
<td>-120,“Numeric data error”</td>
<td>Expected number but other characters were detected.</td>
</tr>
<tr>
<td>-203,&quot;Command Protected&quot;</td>
<td>Password must be CENabled.</td>
</tr>
<tr>
<td>-221,&quot;Settings Conflict&quot;</td>
<td>Calibration state not enabled but CALibrate command received; or LIST:DIR set to DOWN.</td>
</tr>
<tr>
<td>-222,&quot;Current, Voltage or Data out of range&quot;</td>
<td>Value (current or voltage) exceeds power supply rating or (data) exceeds acceptable command parameters.</td>
</tr>
<tr>
<td>-223,&quot;Too Much Data&quot;</td>
<td>During a LIST command, the list became full, preventing all the data from being added to the list.</td>
</tr>
<tr>
<td>-226,&quot;Lists not same length&quot;</td>
<td>During a LIST command, number of DWEL list entries was not equal to 1 and did not match number of LIST:VOLT or LIST:CURR entries.</td>
</tr>
<tr>
<td>-240,&quot;Hardware error&quot;</td>
<td>Power supply did not respond to command.</td>
</tr>
<tr>
<td>-241,&quot;Hardware missing; Discovery Only&quot;</td>
<td>Access to the visa:instr VXI-11 interface was attempted. This functionality is for discovery of the device only, use ni MAx manual entry to establish the socket type device at port 5025.</td>
</tr>
<tr>
<td>-301,&quot;Voltage Error&quot;</td>
<td>Voltage output not within error window; unit set to output off -- only valid for DIAG:ERR 1, 2 or 3 mode (see PAR. and Table 4-2).</td>
</tr>
<tr>
<td>-302,&quot;Current Error&quot;</td>
<td>Current output not within error window; unit set to output off -- only valid for DIAG:ERR 1, 2 or 3 mode (see PAR. and Table 4-3).</td>
</tr>
<tr>
<td>-311,&quot;Memory Error&quot;</td>
<td>*SAV (save), *RCL (recall), or CALibrate:STORE error.</td>
</tr>
<tr>
<td>-350,&quot;Queue Overflow&quot;</td>
<td>Error queue was full, error events have been lost.</td>
</tr>
<tr>
<td>-400,&quot;QueryError&quot;</td>
<td>Data requested was lost due to 253 character limit of BIT 802E output buffer.</td>
</tr>
<tr>
<td>-420,&quot;Query Unterminated&quot;</td>
<td>Controller sent query but did not accept data from power supply. See VOLT? (PAR. B.58), CAL:SAVE (PAR. B.58) commands</td>
</tr>
</tbody>
</table>

(1) The Device error bit may be set when the status monitoring functions of the power supply detect an overvoltage/undervoltage condition.
B.86 SYSTEM:SET COMMAND

Syntax:
Short Form: SYSTEM:SET {CM0 | CM1 | DC0 | DC1 | LF0 | LF1 | RO0 | RO1}
Long Form: SYSTEM:SET {CM0 | CM1 | DC0 | DC1 | LF0 | LF1 | RO0 | RO1}

Description: Establishes Device Clear, Line Feed, and Reset functions. Sending SYSTEM:SEC:IMM sets LF1, DC0, and RO0 (as if CM0 was sent).

DC0 Device Clear functions per IEEE 488.2 Standard: No effect on the device (power supply), only clears internal status registers.
DC1 Device Clear functions identical to *RST: Output set to 0V, voltage mode and output set to OFF except if RO1 (see below) is set.
LF0 Line Feed not provided upon empty buffer condition.
LF1 Line Feed provided if buffer is empty and a read is performed.
RO0 *RST and power up set output to OFF, 0V, 0A, voltage mode.
RO1 *RST sets output to ON, 0V, 0A, voltage mode. Subsequent VOLT and CURR commands are immediately present at the output without sending OUTP ON (OUTP OFF and OUTP ON function normally to turn the output off or on).
CM0 Establishes DC0, LF0, RO0 conditions described above (SCPI 1997 Standard compliance).
CM1 Establishes DC1, LF1, RO1 conditions described above. (Compatible with software versions 1.2 and earlier.) (See example, Figure B-8.)

B.87 SYSTEM:SET? QUERY

Syntax:
Short Form: SYSTEM:SET?
Long Form: SYSTEM:SET?

Return Value: DC<n>,LF<n>,RO<n> where n = 0 or 1

Description: Identifies functions established by SYSTEM:SET command. (See example, Figure B-8.)

B.88 SYSTEM:VERSion? QUERY

Syntax:
Short Form: SYSTEM:VERS?
Long Form: SYSTEM:VERSion?

Return Value: <int_value>.<int_value> (YYYY.V)

Description: Identifies SCPI Version implemented. Returns SCPI Version number: YYY = year, V = Revision number for specified year. (See example, Figure B-8.)
